WITH all the different amounts of sulphur applied (300—1200 lb. per acre) there was an increase in soil acidity as measured by the hydrogen-ion concentration, and this was accompanied by a decided increase in the number of clean tubers. In no case, however, was scab entirely eliminated. The amount of sulphur which gave the most satisfactory results depended to some extent on the hydrogen-ion concentration of the water extract of the original soil. Where this was $p_H = 5.8$ or less, the lighter applications (300—500 lb. per acre) gave approximately as good results as the heavier applications (700—1200 lb. per acre).—W. G.

Titanium; Distribution of — in soils and plants. Geilmann. *J. Landw.*, 1920, 68, 107—121.

SOILS contain from traces to 1% of TiO_2 , the usual amount being 0.3—0.6%. Nearly all of a number of plants examined were found to contain titanium, mostly in the green parts. Plant ashes contain from traces to 0.27% of TiO_2 .—T. H. P.

Fertilisers; Carriers of nitrogen in —. C. E. Thorne. *Soil Sci.*, 1920, 9, 487—491.

RESULTS of field trials extending over periods of 16—25 years show that, with only two exceptions in the forty comparisons, sodium nitrate has produced the largest yield, except on limed land, where the yields from ammonium sulphate slightly exceeded those from the sodium nitrate. The other forms in which nitrogen was supplied for com-

parison were linseed oil meal, dried blood, and tankage.—W. G.

Manures; Investigation of the action of —. O. Lemmermann. *Biedermann's Zentr.*, 1920, 49, 291—310.

A CONTINUOUS series of experiments with nitrogenous, phosphatic, potash, and lime fertilisers and stable manure showed that generally the fertilisers had at first but little effect on the crop yields, the exception being the effect of the nitrogenous manures.—W. P. S.

PATENTS.

Soils; Composition for artificially inducing mould action in —. R. W. Parramore. U.S.P. 1,347,401, 20.7.20. Appl., 11.8.19.

A VEGETABLE meal made from dried and ground leaves and stems of green or immature plants is mixed with ground inorganic fertilising material. J. H. L.

Fertiliser, and process for making same. J. N. Carothers, Assr. to N. D. Baker. U.S.P. 1,350,591, 24.8.20. Appl., 14.1.20.

CALCIUM phosphate is treated with nitric acid containing more than 40% HNO_3 , after which sufficient calcium cyanamide containing free lime is added to convert the monocalcium phosphate into dicalcium phosphate.—W. J. W.

Atmosphere surrounding plants; Process for enriching with carbon dioxide the —. F. Riedel. G.P. 312,793, 14.5.16.

WASTE gases from furnaces and the like are purified by removal of dust, soot, oil, tar, sulphur compounds, etc., and led into the atmosphere in the neighbourhood of plants.—L. A. C.

Seeds; Mixtures for treating —. Chem. Fabr. L. Meyer. G.P. 312,797, 17.8.18.

THE germinating power of the seeds is increased by the addition of mercury or silver salts, e.g., mercuric chloride, to the usual mixtures containing tar or tar-oils used for treating them.—L. A. C.

Fertilisers; Nitrogenous —. Norsk Hydro-Elektrisk Kvaestofaktieselskab. E.P. 139,462, 9.2.20. Conv., 24.2.19.

SEE U.S.P. 1,340,708 of 1920; J., 1920, 498A.

XVII.—SUGARS; STARCHES; GUMS.

Cane juice and syrups; Relative importance of some colouring matters in sugar —. F. W. Zerbau. *J. Ind. Eng. Chem.*, 1920, 12, 744—751. (*Cf. J.*, 1918, 778A.)

THE dark colour of sugar cane juice appears to be due almost entirely to the presence of several polyphenol derivatives; when ferric salts are present, as is almost always the case with factory products, the colour is two or three times as dark as with polyphenols alone. A tannin, which gives a green colour with ferric salts, is present, but its influence on the colour of the juice is supplemented by that of the polyphenol derivatives, e.g., anthocyanin and saccharatin.—W. P. S.

Sugar; Prevention of the deterioration of raw — by the use of superheated steam in the centrifugals. N. Kopeloff. *J. Ind. Eng. Chem.*, 1920, 12, 860—862.

MASSECUITE inoculated with micro-organisms known to be active in causing the deterioration of raw sugar (*J.*, 1918, 275A; 1919, 539A) was centrifuged and treated with superheated steam while still in the machine, the temperature of the product thus being raised to 65°—70° C. A diminution of 99.5%

of the bacteria, and 98.3% of the moulds, originally present in the massecuite was thus effected; while in the case of the separated molasses the figures were 84.3 and 50.0% respectively. (Cf. Shorey, J., 1898, 555.)—J. P. O.

Sugars; Iodometric estimation of — H. M. Judd. *Biochem. J.*, 1920, 14, 255—262.

THE polarimetric method is unreliable for the estimation of levulose in fruit juices. The iodometric methods of Colin and Liévin (J., 1918, 745 A) and of Willstätter and Schudel (J., 1918, 556 A) for the determination of dextrose in presence of levulose do not give accurate results, since only about 95% of the dextrose is oxidised, whilst the levulose is definitely attacked. It has been found, however, that a given weight of dextrose or levulose always reacts with a definite weight of iodine; in neither case is the amount affected by the presence of other sugars or by the concentration of the alkali, and the iodine equivalents of mixtures calculated from the constants agree with the observed values. Willstätter and Schudel's method may therefore be used for the analysis of mixtures of dextrose and levulose if the results be interpreted from the calculated iodine equivalents and the copper-reducing power of the mixture. The iodine equivalents of 1 g. of each of the following sugars has been calculated: Dextrose, 1.315 g.; levulose, 0.1028; mannose, 0.977; galactose, 1.418; arabinose, 1.702; rhamnose, 0.9243; lactose, 1.502; maltose, 0.7456 g. Sucrose is not oxidised by iodine under the conditions named.—J. C. D.

Saccharimeters; Testing of — by means of the telescopic control tube. C. A. Browne. *J. Ind. Eng. Chem.*, 1920, 12, 792—796.

THE control tube consists of a telescopic metal tube which can be adjusted by a screw to give a column of solution of any length between 225 and 410 mm. By means of a vernier the exact length of solution at any point within this range can be read on the scale to 0.1 mm. The tube may be used for determining the errors of saccharimeter scales, for comparing the scales of different instruments and their comparative accuracy, for determining the probable error of those who use the instrument, and for determining the influence of personal equation in the observations. The average probable error for a single reading upon the Schmidt-Haensch and Fric saccharimeters is found to be ± 0.0514 and ± 0.0286 , respectively. The author confirms the opinion of Landolt that the quartz-wedge saccharimeter contains inherent defects which prevent it from becoming an instrument of the highest precision.—W. P. S.

Carbonatation sludge cakes [in sugar factories]; Composition of — and new means for their more efficient washing. A. Müller. *Z. Zuckerind. Czechoslov.*, 1920, 44, 374—376.

IN filter-presses operated by a cylinder pump the fluctuations of pressure due to the stroke of the pump necessitate the use of stronger and denser filter cloths than would be required with a uniform pressure, and also facilitate the deposition of sand and coarse particles, which consequently form a relatively permeable layer at the bottom of the filter chambers, and render difficult the effective washing of the upper part of the cakes. By means of a combined pneumatic shock absorber and sand remover devised by the author, which is mounted on the suction or pressure side of the pump, and utilises part of the pressure pulse to effect a rotary motion of the liquid, sand may be removed centrifugally. The relatively great permeability of the layer of sand and coarse particles at the bottom of the filtering chambers may also be counteracted by increasing the resistance of the bottom of the filters, e.g., by means of a strip of non-perforated

or finely perforated metal, or by sewing a strip of denser cloth along the bottom of each filter cloth.

—J. H. L.

Fructose [levulose]; Specific rotation of —. W. C. Vosburgh. *J. Amer. Chem. Soc.*, 1920, 42, 1696—1704.

THE specific rotation of levulose solutions over the concentration range 2.6—20 g. per 100 c.c. is given by $[\alpha]_D^{25} = -(88.50 + 0.145p)$ or $[\alpha]_D^{25} = -(88.50 + 0.150c - 0.00086c^2)$, where p and c represent the concentration of the sugar in % and g. per 100 c.c. respectively. Over the temperature range 15°—37° C. the variation of $[\alpha]_D$ with temperature is given by $[\alpha]_D^t = [\alpha]_D^{25} + (0.566 + 0.0028c)(t - 25)$. For most purposes the rotations with the D line may be converted into those for the line $\lambda = 546\mu$ by $[\alpha]_D^t \lambda = 1.1809[\alpha]_D^t$.—W. G.

Fat associated with starch. T. C. Taylor and J. M. Nelson. *J. Amer. Chem. Soc.*, 1920, 42, 1726—1738.

CORN (maize) starch, carefully freed by extraction from all adherent or associated fat, gave on hydrolysis about 0.56% of "fat by hydrolysis," the two main constituents of which were palmitic acid and an unsaturated compound of unknown constitution. This fat is apparently liberated when the hydrolysis has reached the erythrodextrin stage. It was obtained in considerable amount from the "refinery mud" in the manufacture of dextrose from starch. Starches of other vegetable origin, e.g., from rice, sago, potato, etc., contained amounts of this fat varying from 0.04 to 0.83%.

—W. G.

Levan; Formation of — by mould spores. N. Kopeloff, L. Kopeloff, and C. J. Welcome. *J. Biol. Chem.*, 1920, 43, 171—187.

SPORES of the mould, *Aspergillus sydowi*, form levan in sucrose media. The sucrose is hydrolysed before utilisation and the levulose and dextrose are utilised, the former to the greater extent, in formation of the gum. It appears necessary that the sugars be present in a "nascent" condition for the synthesis to be possible, as little gum formation occurs in media containing reducing sugars from ordinary sources. The synthesis by the enzyme, levanase, is influenced by the reaction of the medium, and has its optimum at about $pH = 7.0$. Levan yields levulose on hydrolysis. (Cf. J.C.S., Oct.)—J. C. D.

Glutamic acid. Skola. See XX.

Alkalimetric titrations. Bruhns. See XXIII.

PATENTS.

Sugar juices and the like; Treatment of —. J. N. A. Sauer. G.P. 322,135, 6.3.19.

THE juices are first subjected to preliminary treatment with a char produced by heating cane bagasse or exhausted beet slices in closed retorts, and then treated with finely powdered decolorising carbon. The latter may be produced from the above-mentioned char by treatment with hot gases in absence of air, or it may be produced directly from cane bagasse or exhausted beet slices by heating in absence of air and simultaneously conducting hot gases through the material. The preliminary treatment of the juices effects a saving in decolorising carbon and facilitates the regeneration of the latter.—J. H. L.

Diffusion process [for extraction of sugar, tannin, etc.]. R. Farkas. G.P. 320,688, 25.5.17.

THE exhaustion of the material in the last unit of a diffusion battery is rendered more complete by introducing the total quantity of fresh solvent for this unit in portions at intervals instead of all at

one time. The corresponding portions of liquor drawn off are collected in a separate receptacle and afterwards introduced together into the preceding unit in the ordinary way.—J. H. L.

Syrup or artificial honey; Preparation of — from crude sugar solutions. W. Meyer. G.P. 319,841, 21.3.18.

CRUDE sugar solutions are inverted by evaporating in acid medium to a high density, and are then diluted, neutralised, filtered, and concentrated: or a strong inverted solution of relatively pure sugar may be mixed with very impure sugar solutions, such as molasses, previous to neutralising and filtering.—G. F. M.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Degeneration and treatment of —. R. Heuss. Z. ges. Brauw., 1920, 43, 225—227, 233—234, 241—242.

A **BOTTOM-FERMENTATION** brewery yeast used in the production of dark, 4·5% war beers, was much improved by treatment with five times its volume of water containing 0·12% of free potassium carbonate for 15 hrs. at about 4° C., followed by two washings with cold water. Compared with the same yeast washed only with water, the treated yeast was much lighter in colour, and its flavour was mild and free from bitterness. In the first fermentation after the treatment it produced a slightly less rapid attenuation than the control yeast, but in subsequent fermentations this difference was reversed. The break or flocculation of the treated yeast occurred at a later stage of fermentation than in the case of the control yeast. The beers produced were milder in flavour but possessed less palateness than those produced by the control yeast. —J. H. L.

Yeast. Nitrogen metabolism in S. cerevisiae. L. H. Lampitt. Biochem. J., 1919, 13, 459—486.

EXCESS of yeast ensures the removal of the greatest total amount of nitrogen. During active fermentation the greater the coefficient of multiplication the greater the amount of nitrogen assimilated by each cell. Active reproduction may result in a lowering of the nitrogen coefficient, even when a large amount of available nitrogen is present. The final nitrogen coefficient of a yeast is independent of the initial coefficient, and tends to reach a value constant for any particular conditions of reproduction. The amidase of Effront (this J., 1908, 462) does not produce solely a volatile acid by its action on asparagine, but also a non-volatile acid, probably malic acid. If this is so, the acid is probably converted into the ammonium salt before it is fermented to alcohol, for the free acid is not fermented. Propionic acid is not fermented by yeast. Fermentative activity is essential to nitrogen assimilation. The two actions are not proportionate, but the former stimulates the latter, and, once induced, desamination may continue after zymatic activity ceases. Excessive zymatic activity does not ensure rapid nitrogen assimilation. During fermentation yeast continually loses nitrogen to the liquid, and this action has been called "nitrogen excretion." This excretion is dependent on the life of the cell, and takes place even when nitrogen is being assimilated. The substances so secreted can be used by the yeast as a source of nitrogen under suitable conditions. Increase in the amount of sugar available for fermentation increases the rate of excretion, and although zymatic activity is necessary for nitrogen excretion, the two are not proportionate, nor does the cessation of the former result in an immediate cessation of the latter.—J. C. D.

Fermentation; Cold —. G. Fries and R. Heuss. Z. ges. Brauw., 1920, 43, 249—252, 257—260.

HEALTHY bottom-fermentation yeast which had been subjected to alkaline treatment (see preceding abstract) was employed in large scale fermentations of 4% and 10% worts at temperatures of 3°—4° C., instead of the usual temperatures of bottom fermentation, viz., 4°—10° C. The results were unsatisfactory; fermentation occupied 1—3 days longer than usual, and although relatively large amounts of yeast were used for pitching, the yeast crops obtained were very small. Moufang's statement that low fermentation temperatures improve the character of the beer produced was not confirmed. In the alkaline treatment of the yeast losses amounting to about 40% were incurred (cf. loc. cit.)—J. H. L.

Acidity [of worts]; Determination of — and titration in stages. H. Lüers. Z. ges. Brauw., 1920, 43, 252—253.

A MODIFICATION of Reichard's method of titration in stages (J., 1917, 399; 1918, 523 A) is described, in which "neutral red" is used instead of litmus paper as the first indicator, in order to enable both stages of the titration to be carried out in the apparatus previously described by the author (J., 1914, 761). The method, as applied to coloured liquids like wort, is thereby rendered much more precise. The colour standard used for the first titration is a permanent dye solution having the same colour as a Sørensen phosphate solution containing 6·5 pts. of secondary to 3·5 pts. of primary phosphate to which 1/10 of its volume of a 0·02% solution of "neutral red" in 50% alcohol has been added. This phosphate solution has $p_H=7·07$ (absolute neutrality), which differs only slightly from the transition reaction for litmus, $p_H=6·8$. The first titration is carried out in an analogous manner to that described for phenolphthalein (*ibid.*), the left hand sample of wort receiving 1/10 of its volume of 0·02% "neutral red" solution. After the first titration has been completed it is necessary to add a similar quantity of "neutral red" to the right-hand sample of wort, since this indicator retains a yellow colour in alkaline solutions. The colour standard is then replaced by the phenolphthalein colour standard (*ibid.*), the left-hand sample of wort is treated with 1/10 of its volume of 0·05% phenolphthalein solution, and the second titration is proceeded with until the end-point ($p_H=9·18$) is attained.—J. H. L.

Wines; Glycerol in —. L. Mathieu. Bull. Assoc. Chim. Sucr., 1920, 37, 423—425.

THE quantities of sulphurous acid commonly employed in vinification were found to have no perceptible influence on the formation of glycerol. Reduction of the acidity of a must by addition of potassium carbonate appreciably reduced the production of glycerol during fermentation, whilst an excess of carbonate equivalent to 0·65% of sulphuric acid slightly increased the yield of glycerol. —J. H. L.

Wine; Analysis of —. W. Fresenius and L. Grünhut. Z. anal. Chem., 1920, 59, 209—232. (Cf. J., 1920, 555 A).

METHODS are given in detail for the determination of ash, total alkalinity of ash, alkalinity of soluble ash, and phosphoric acid.—W. P. S.

Volatile acids; Determination of — in fermentation products. G. Hinard. Ann. Chim. Analyt., 1920, 2, 239—242.

FIFTY c.c. of the sample is mixed with 10 c.c. of water and distilled, 50 c.c. of distillate being collected and titrated; 50 c.c. of water is then added to the residue in the distillation flask, the mixture distilled as before, and these operations are

repeated several times. When the results are plotted graphically, using the volumes of the distillates (50 c.c.) as abscissæ and the quantities of standard alkali solution used for the successive titrations as ordinates, the asymptote of the curve indicates the volume of alkali solution necessary to neutralise the amount of volatile acids contained in the 50 c.c. of the sample.—W. P. S.

Alcohol; Losses of — in distilleries. *Methods of recovery.* Mariller. Bull. Assoc. Chim. Sucr., 1920, 37, 412—423.

THE alcohol entrained by fermentation gases from closed or open vats may be recovered by using cresol as absorbent (*cf.* Brégeat, E.P. 128,640 and 131,938, J., 1919, 612A, 751A). Cresol may also be used for the absorption of volatile products from the distillation of wood, peat, lignite, etc. It has been successfully applied to the recovery of alcohol and ether in perfumery.—J. H. L.

Yeast growth-promoting stimulus. Emmett and Stockholm. See XIXA.

PATENTS.

Glycerol; Manufacture of — from sugar. Verein. Chem. Werke A.-G. E.P. 138,331, 21.1.20. Conv., 18.6.17. Addn. to 138,099.

IN the process claimed in the chief patent and in E.P. 138,328 (J., 1920, 608A), when the fermentation has attained its height a further quantity of sugar is added, if necessary, together with a small proportion of yeast and alkaline compounds, preferably sulphites, with or without other salts. This effects a considerable saving in respect of yeast, sulphite, and time.—J. H. L.

Spirits and alcoholic liquors; Process and apparatus for ageing —. A. Jarraud. E.P. 141,687, 31.3.20. Conv., 17.4.19.

THE liquid is subjected to electrolysis by means of an anode of non-oxidisable material and a depolarising cathode (*e.g.*, a carbon rod surrounded by manganese dioxide in a porous cell), with a current-density of 0.5—1 milliampère-hr. per sq. cm. of anode surface. If necessary, oak shavings may be interposed in the path of the current in the neighbourhood of the anode. For the treatment of spirits and the like, in new casks, a tubular cathode may be inserted through the bung-hole, and the anode may consist of sheets of metallic foil secured to the outer surface of the cask. Pads of moist cloth may be interposed between the foil and the wood to reduce the resistance of the latter.

J. H. L.

Fat; Production of mould fungi of all kinds rich in —. Reichsausschuss für pflanzliche und tierische Öle und Fette, G.m.b.H. G.P. 320,560, 2.9.17. (*Cf.* J., 1920, 417A.)

IN the production of fat by cultivation of mould fungi in nutrient liquids rich in sugar but of low nitrogen-content, the mould cells are maintained thinly distributed throughout the liquid (*e.g.*, corresponding to a "pitching" of 20 g. of moist pressed mould per litre), local accumulation of cells being avoided. Yeast containing 40—50% of fat may be produced.—J. H. L.

Fat from sulphite-cellulose lyes. G.P. 305,091. See XII.

Calamus root. G. P. 307,623. See XX.

XIXA. FOODS.

Wheat flour; Heat of hydration and specific heat of —. F. Daniels, B. H. Kepner, and P. P. Murdick. J. Ind. Eng. Chem., 1920, 12, 760—763.

THE heat of hydration of various Canadian and American wheat flours ranged from 5.4 to 7.6

B.Th.U. per lb.; flour generally used for bread-making gave a value of 6.5 B.Th.U. per lb.; the heat of hydration decreased when the flour was exposed to the atmosphere, but did not change appreciably with age when the flour was isolated completely from air. The specific heat of flour was found to be 0.43.—W. P. S.

Butter and certain allied products; Volumetric method for the detection and determination of neutralisers in —. L. W. Ferris. J. Ind. Eng. Chem., 1920, 12, 757—759.

THE greater part of the fat is separated from 100 g. of butter by treatment with petroleum spirit and centrifugal action, the aqueous portion is mixed with a known amount of *N*/10 hydrochloric acid and an excess of picric acid solution, filtered, the lactic acid and excess of picric acid are extracted with ether, and the residual solution is titrated with *N*/10 sodium hydroxide solution, using methyl orange as indicator. The difference between the volume of acid added and that of the alkali solution used for the neutralisation will be a measure of the alkalinity of the salts or the amount of acid that has combined with the bases formerly present as alkalis, lactates, and phosphates. The phosphoric acid is then determined in the neutralised solution. In normal milk and cream the alkalinity of the salts bears a definite ratio to the inorganic phosphoric acid, being about 45 c.c. of *N*/1 solution to 1 g. P_2O_5 ; in neutralised cream this ratio is increased to a degree dependent on the amount of alkali added and the P_2O_5 content of the sample. Butter made from neutralised cream has an alkalinity ratio similar to that of the cream from which it was made. If, however, the acidity of the cream is reduced to less than 0.3% it is not sufficient to keep all the phosphate in solution, and the butter may then have a lower alkalinity ratio than the neutralised cream.—W. P. S.

Eggs; Preservation of —, including a bibliography of the subject. H. I. Jones and R. Du Bois. J. Ind. Eng. Chem., 1920, 12, 751—757.

COLD storage of eggs is successful only when the surrounding atmosphere is dry and the eggs are kept dry; low temperature merely inhibits bacterial etc. growth and is not germicidal. The most satisfactory method consists in coating the eggs, and for this purpose a solution of aluminium soap in pure pentane is recommended; if gasoline is used in place of pentane the eggs must be treated previously with dilute sulphuric acid to prevent penetration of the objectionable odour and taste of the gasoline.—W. P. S.

Caseins; Behaviour of different — as regards their increase in viscosity [when heated]. C. Chorower. Chem.-Zeit., 1920, 44, 605—606, 613—614.

WHEN cows' milk is evaporated under reduced pressure, as in the manufacture of condensed milk, and then maintained at about 58° C. for 35—40 mins., the viscosity shows an increase during this heating period of three to four times the value at the commencement. This increase is a function of the temperature, time of heating, and concentration, and is due to changes in the casein. The other constituents of the milk do not appreciably alter in viscosity. The casein of goats' milk, unlike that of cows' milk, does not increase in viscosity when its concentrated solution is subjected to prolonged heating, and admixture of goats' milk with cows' milk reduces the viscosity of the finished condensed product.—W. P. S.

Tyrosine; Colorimetric estimation of — by the method of Folin and Denis. R. A. Gortner and G. E. Holm. J. Amer. Chem. Soc., 1920, 42, 1678—1692.

THE phenol reagent of Folin and Denis (J. Biol.

Chem., 1912, 12, 245) cannot be used for the estimation of tyrosine in protein hydrolysates. Tryptophane (and probably other products of protein hydrolysis), if present, will give a blue colour with the reagent. Indole and its derivatives and ferrous salts also give a blue colour. The intensity of the blue colour produced by tyrosine varies with the relative amounts of tyrosine and reagent present. Protein hydrolysates must not be decolorised by carbon or bone black if they are to be used subsequently for the estimation of amino-acid content, as tyrosine, tryptophane and its decomposition products are adsorbed in appreciable amounts by bone black. Bone black itself contains some easily oxidisable material which dissolves in acid solutions and then gives a blue colour with the phenol reagent.—W. G.

Inulin in the globe artichoke. R. Okey and A. W. Williams. J. Amer. Chem. Soc., 1920, 42, 1693—1696.

In a sample of globe artichokes which contained 6—8% of nitrogen-free extractives as measured by difference after the estimation of moisture, ash, crude fibre, crude protein, and ether extract, the authors found probable inulin, 2.5% and total carbohydrate extracted by water and 1% hydrochloric acid, 4.2%.—W. G.

Vitamines; Water-soluble, anti-neuritic, and growth-promoting B — A. D. Emmett and G. O. Luros. J. Biol. Chem., 1920, 43, 265—286.

The authors' results tend to support the theory that these substances are not identical. (Cf. J.C.S., Oct.)—J. C. D.

Vitamines; Relation of water-soluble, anti-neuritic, and water-soluble B — to yeast growth-promoting stimulus. A. D. Emmett and M. Stockholm. J. Biol. Chem., 1920, 43, 287—291.

FURTHER evidence is given that vitamin B and the anti-neuritic factor are not identical. Possibly the substance stimulating the growth of yeast is also distinct.—J. C. D.

Vitamine content; Studies in — W. H. Eddy and H. C. Stevenson. J. Biol. Chem., 1920, 43, 295—309.

THE authors propose a modification of the processes devised by Bachmann and by Williams (J., 1920, 608A) for the quantitative estimation of extracts containing the vitamin B, and show that its use may throw light upon the relative values of food-stuffs as sources of this vitamin.—J. C. D.

Albumoses. Nagayama. Sec XX.

PATENTS

Milk products; Manufacture of artificial — N. V. A. Jurgens' Vereen. Fabrieken. E.P. 128,544, 23.4.19. Conv., 18.0.18.

ARTIFICIAL milk or cream possessing the natural flavour is prepared by emulsifying vegetable or animal fats or fatty mixtures in skim milk or an artificial albuminous solution the acidity of which has been reduced, by partial neutralisation, to not more than 5° Soxhlet-Henkel (equivalent to 5 c.c. of N/4 alkali per 100 c.c.). Pure cultures of bacteria or other substances may be added to improve the flavour.—J. H. L.

Protein and phosphates of calcium and magnesium; Process for recovering — from acid waste waters. A. Giesecke. U.S.P. 1,348,990, 10.8.20. Appl., 10.3.19.

ACID waste water from corn steeping is neutralised partially with milk-of-lime in order to precipitate a mixture of proteins and calcium and magnesium phosphates.—W. P. S

Jam; Preparation of — from fruit or other vegetable constituents. O. and C. Biemann. G.P. 313,768, 9.8.18. Addn. to 303,995 (J., 1920, 525A).

THE solution of sugar and fruit juice obtained from the diffusion vessel freshly filled with fruit is heated and further sugar is added to bring the concentration up to that of the original sugar solution employed. The solution is then returned to the diffusion vessel containing the extracted fruit instead of fresh sugar solution.—G. F. M.

Syrups and jellies from fruits or other vegetable products; Preparation of — O. and C. Biemann. G.P. 318,266, 9.8.18. Addn. to 303,995 (J., 1920, 525A).

SYRUPS containing a definite proportion of sugar are obtained by passing the juice coming from a diffusion battery through a vessel containing coarse sugar crystals at a definite speed or temperature or both.—C. A. M.

Lupins; Production of a feeding stuff rich in proteins from — H. Thoms and H. Michaelis. G.P. 320,559, 7.9.17. Addn. to G.P. 307,007 (J., 1919, 597A).

THE treatment with alkali precedes extraction of the bitter substances with alcohol.—J. H. L.

Fruit juices; Process of treating — J. G. F. Hieber. E.P. 149,537, 17.9.19.

SEE U.S.P. 1,325,094 of 1919; J., 1920, 170A.

Wheat and other cereals and their products; Apparatus for separating and purifying — J. Higginbottom. E.P. 149,020, 10.10.18 and 9.4.19.

Boiling pans for manufacture of confectionery; Installation of — R. S. and T. N. McColl and T. F. Dryden. E.P. 149,172, 9.12.19.

XIXB.—WATER PURIFICATION; SANITATION.

Cyanogen chloride; Mechanism of the toxic action of — C. I. Reed. J. Pharm. Exp. Ther., 1920, 15, 301—304.

THE symptoms following poisoning with cyanogen chloride are typical of poisoning with hydrocyanic acid. Sodium thiosulphate exerts a protective action in both cases by the formation of non-toxic sodium thiocyanate. In cases of delayed poisoning by cyanogen chloride it is possible that the toxic action of the chlorine also plays a part.—J. C. D.

Chloropierin; Destruction of white ants by — J. Feytaud. Comptes rend., 1920, 171, 440—442.

EXPOSURE at 20° C. for 12 hrs. to an atmosphere containing 2 mg. of chloropierin per l., or for 6 hrs. in an atmosphere containing 5 mg., is sufficient to destroy white ants (*Leucotermes lucifugus*, Rossi) either freely exposed or in fragments of wood 10 cm. thick.—W. G.

PATENTS.

Water-softening compound and method of producing same. G. L. Borrowman. U.S.P. 1,348,977, 10.8.20. Appl., 2.6.16. Renewed, 8.5.19.

A WATER-SOFTENING material consists of a "natural base exchange silicate" stabilised by baking to render it capable of resisting the powdering action of flowing water.—L. A. C

Water purified with chlorine; Removing iron from —. Th. Goldschmidt A.-G. G.P. 319,963, 31.12.13.

APPRECIABLE amounts of iron are retained in a colloidal form by water after the iron treatment following chlorine purification. The iron can be removed by passing the water through a sand filter.—W. J. W.

Boiler-feed water; Process of removing gases from, softening, and preheating —. J. P. Winer. G.P. 320,423, 1.12.16. Addn. to 302,643 (J., 1918, 440 A).

The feed water from the nozzles is sprayed into a part of the receptacle in the upper part of the boiler, separated by a partition, and from this it passes through the external tubular extension to the lower part of the boiler.—W. J. W.

Liquids; Purification of — by means of colloidal silicic acid. O. Biemann. G.P. 320,846, 22.11.16.

LIQUIDS are treated with silicic acid prepared by passing carbon dioxide into dilute sodium or potassium silicate solution and filtering. The colloidal silicic acid obtained may be purified before use by means of water containing carbon dioxide in solution, the product being absolutely tasteless and without smell.—W. J. W.

Sterilising liquids by means of chlorine; Process and apparatus for —. E. Volland. G.P. 305,888, 14.7.15.

THE liquid to be sterilised, supersaturated with chlorine, is transferred in a fine spray to a vessel in which a vacuum is maintained, and is thereby freed from the excess of chlorine.—G. F. M.

Sterilising agent; Preparation of a powerful solid —. A. Pieroni, and Soc. Chim. Lombarda A. E. Bianchi & Co. G.P. 320,795, 9.1.17. Conv., 5.1.16.

A CHLORATE is mixed in the cold in a closed vessel, under pressure, with chlorine and iodine, or materials capable of giving iodine under the action of chlorine and an acid. The reaction, which is carried out in the dark, or in red light, is assisted, if necessary, by heating. The product is crystalline, and probably has the composition KIO_2 . —G. F. M.

Refuse; Treatment of — in refuse destructors and the production and treatment of a fluid slag obtained therefrom. J. B. C. Kershaw. E.P. 149,033, 11.10.19.

A SLAG which is fluid at 1260° – 1370° C. is produced in refuse destructors by mixing the refuse with limestone, chemical waste, road sweepings or other material containing lime, so that the resulting slag contains 40% SiO_2 and 15% $\text{CaO} + \text{MgO}$. If necessary, slack, coke or other combustible material may also be added, and an air-blast may be used so as to increase the temperature in the destructor. A jet of steam may be allowed to play on the stream of molten slag issuing from the destructor so as to form a fine amorphous powder which is ready for use as an aggregate for concrete or mortar. Alternatively, the molten slag may be run into moulds so as to form blocks for building purposes.—A. B. S.

Waste liquors. G.P. 322,461. See V.

Soapy liquors. U.S.P. 1,349,530. See XII.

Treating seeds. G.P. 321,797. See XVI.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Glucosides; Extraction of — from two indigenous orchids; identification of these glucosides with loroglossin. P. Delauney. Comptes rend., 1920, 171, 435–437.

A CRYSTALLINE glucoside obtained from *Orchis Simin*, Lam., and *Ophrys aranifera*, Huds., is shown to be identical with loroglossin obtained from *Loroglossum hircinum*, Rich., by Bourquelot and Bridel (J., 1919, 337 A).—W. G.

Spilanthal, the pungent principle of Para cress (Spilonthes oleracea). Y. Asahina and M. Asano. J. Pharm. Soc., Japan, 1920, 503–515.

CRUDE spilanthal was prepared (yield ca. 1%) from air-dried flower-heads of the plant by Gerber's method (Arch. Pharm., 1903, 241, 270). The base, $\text{C}_8\text{H}_{11}\text{N}$, formed by heating it with alcoholic hydrogen chloride, proved to be isobutylamine. Hydrosplanthal, prepared by hydrogenating crude spilanthal in acetic acid solution in presence of platinum black, is a colourless viscous liquid which solidifies to crystals, m.p. 28° C. It is probably a mixture of two substances, $\text{C}_{13}\text{H}_{27}\text{NO}$ and $\text{C}_{11}\text{H}_{23}\text{NO}$. When heated with alcoholic hydrogen chloride in a sealed tube it yields isobutylamine and a saturated fatty acid, m.p. 28° C., and b.p. 136° – 140° C. at 4 mm; probably a mixture of decolic acid, m.p. 31.5° , and nonoic acid, m.p. 12.5° C.—K. K.

Viburnum prunifolium; Some constituents of —. F. W. Heyl and C. Barkenbus. J. Amer. Chem. Soc., 1920, 42, 1744–1755.

THE dried root bark of *Viburnum prunifolium* ("black haw") contained moisture 7.1%, ash 7.3%, ligroin extract 7.1%, ether ext. 10.4%, and alcohol extract 18.7%. Acetic and valeric acids were present in the free state, as water-soluble complex esters, and as resinous esters insoluble in water. From the resin insoluble in water a new phyto-sterol, m.p., 186° – 187° C.; $[\alpha]_D^{20} = +115^\circ$ (in chloroform) was isolated, giving an acetate, m.p., 223° – 224° C. The fat from this resin contained formic, acetic, caproic, caprylic, myristic, palmitic, oleic, and linolic acids, but no valeric acid. A trace of an amorphous alkaloid was found in the alcoholic extract of the drug.—W. G.

Pseudo-muscarine ("synthetic muscarine"). A. B. Weinhausen. J. Amer. Chem. Soc., 1920, 42, 1670–1678.

THE products obtained in the preparation of "synthetic muscarine" by the action of nitric acid on choline platinichloride vary considerably with the conditions. If the original directions of Schmeideberg and Harnack (Arch. exp. Path. Pharm., 1877, 6, 101) are adhered to the main product is choline nitrate platinichloride. (Cf. J.C.S., Oct.).—W. G.

Ferrous zymophosphate. K. Schweizer. Bull. Assoc. Chim. Sucr., 1920, 37, 464–468.

FOLLOWING Euler's method (cf. F.P. 458,096; J., 1913, 1031) for the preparation of salts of hexose-phosphoric acid, the author obtained a ferrous compound in the form of a greyish-green amorphous powder, tasteless and odourless, and insoluble in water and ordinary organic solvents but decomposed by mineral acids or sodium hydroxide. Administered to guinea-pigs it was in part decomposed in the stomach, but the undecomposed portion passed through the intestines unchanged.

—J. H. L.

Phytic acid; Synthesis of — R. J. Anderson. *J. Biol. Chem.*, 1920, 43,, 117—128.

THE product obtained by interaction of inositol, phosphoric acid, and phosphorus pentoxide appears to be an inositoltetraphosphoric acid, and is not identical with natural phytic acid or inositolhexaphosphoric acid.—J. C. D.

Adrenaline; Colorimetric determination of — W. L. Scoville. *J. Ind. Eng. Chem.*, 1920, 12, 769—771.

A Mixture of water, 20, 1% potassium iodate solution, 5, and N/1 hydrochloric acid 0.25 c.c., is heated to 38° C. and 0.5 c.c. of the adrenaline solution to be tested (this may be a 0.1% solution) is added. A similar standard mixture is made at the same time with pure adrenaline. Both mixtures are heated at 38° C. for 15 mins., then cooled, and the colorations compared. If the coloration of the test solution differs by more than 25% from that of the standard, the determination should be repeated, using more or less of the test solution. If the test solution contains bisulphite, 0.05 g. of sodium bisulphite must be added to the standard solution, which is prepared by dissolving 0.05 g. of pure adrenaline in 0.5 c.c. of N/1 hydrochloric acid and diluting to 50 c.c. The results obtained agree with those yielded by the biological method.—W. P. S.

Phenolphthalein; Iodometric method for the determination of — S. Palkin. *J. Ind. Eng. Chem.*, 1920, 12, 766—769.

UNDER suitable conditions, phenolphthalein when treated with iodine gives a quantitative yield of tetraiodophenolphthalein. The phenolphthalein (not more than 0.25 g.) is dissolved in the minimum amount of 30% potassium hydroxide solution in water, 20 g. of ice is added, and an excess of iodine reagent is introduced; about 10 c.c. is sufficient. (The reagent is prepared by dissolving iodine in 15% potassium iodide solution to make a 10% iodine solution and then discharging the colour of the iodine by the addition of alkali.) The mixture is then treated, drop by drop, with concentrated hydrochloric acid until precipitation is complete, more iodine is added if the supernatant liquid is not brown in colour, the precipitate is dissolved by the addition of 30% potassium hydroxide solution, and the re-precipitation and re-solution are repeated three or four times. The final alkaline solution is treated with 0.5 c.c. of 15% sodium sulphite solution and a few c.c. of hydrochloric acid, and extracted several times with acetone-chloroform (1:3) mixture. The united extracts are evaporated, the residue of tetraiodophenolphthalein thus obtained dried at 100° C. for 20 mins., and weighed; the weight multiplied by 0.3781 gives the amount of phenolphthalein. To determine the latter in tablets which contain chocolate, the sample is ground, extracted for 2 hrs. with petroleum spirit to remove fat, the phenolphthalein then extracted with acetone, the acetone solution evaporated, the residue dissolved in potassium hydroxide solution, and the process continued as described.—W. P. S.

Albumoses; Histamine and a histamine-like substance as decomposition products of — T. Nagayama. *J. Pharm. Exp. Ther.*, 1920, 15, 401—414.

THE proteoses of commerce vary in toxicity. A secondary albumose was prepared from fresh thyroid glands by means of peptic digestion. Under certain conditions hydrolysis with acids causes the appearance of an appreciable quantity of histamine, and also of a histamine-like substance. Attention is called to the large amount of chloro-

form-soluble matter obtained in the hydrolysis of the proteoses studied.—J. C. D.

Aminoacetanilide; Preparation of — A. J. Hill and E. B. Kelsey. *J. Amer. Chem. Soc.*, 1920, 42, 1704—1711. (Cf. Dubsky and Gränacher, *Ber.*, 1917, 50, 1701.)

AMINOACETANILIDE is best prepared by a modification of Majert's process (E.P. 5269 of 1891; *J.*, 1892, 369). 550 g. of chloroacetanilide is added to 11 kg. of 95% alcohol previously saturated with ammonia at 10° C., and the mixture left to stand for 5 days at 20° C. It is then evaporated under diminished pressure to $\frac{1}{4}$ of its volume and poured into 3500 c.c. of water. An oil separates and solidifies. This is the secondary base which is filtered off. The filtrate is evaporated nearly to dryness and the residual material dissolved in hot water. After decolorising, the solution is cooled in ice and saturated with ammonia when aminoacetanilide crystallises out. Satisfactory yields could not be obtained by Majert's second process (*loc. cit.*) from aniline and ethyl aminoacetate hydrochloride.—W. G.

Cinnamic acid; Identification of — Denigès. *Bull. Soc. Pharm. Bordeaux*, 1919. *Ann. Chim. Analyt.*, 1920, 2, 245—246.

A DISTINCT odour of benzaldehyde is obtained when 2 c.c. of cinnamic acid solution (containing as little as 0.02 mg. of the acid) is treated with 1 drop each of ferric chloride solution, 10% sulphuric acid, and hydrogen peroxide solution (2 vol.), and then heated. In the case of cinnamic esters, Peru balsam, etc., a preliminary saponification with a few drops of sodium hydroxide solution is required.—W. P. S.

Glutamic acid and its salts; Decomposition of — on heating. V. Skola. *Z. Zuckerind. Czechoslov.*, 1920, 44, 347—351, 355—360, 363—368, 370—374.

ON recrystallising glutamic acid obtained by Andrlik's method from molasses (*J.*, 1915, 1064), non-crystallisable syrupy mother liquors were obtained, owing to the formation of the corresponding lactam, *l*-glutimic acid (cf. Stanek, *J.*, 1912, 1001). Such syrups were successfully treated by saturating with hydrochloric acid whereby the glutimic acid was converted into the hydrochloride of glutamic acid, which crystallised. The nitrogen of glutamic acid can be determined almost quantitatively by "formol-titration" provided successive additions of formaldehyde are made alternating with neutralisation of the acidity developed by each addition. Glutimic acid scarcely reacts with formaldehyde. (Cf. *J.C.S.*, Oct.)—J. H. L.

Urea; Determination of — by xanthhydrol. Frenkel. *Ann. Chim. Analyt.*, 1920, 2, 234—239.

TEN c.c. of a 10% solution of urino is treated with 35 c.c. of glacial acetic acid and 10% xanthhydrol solution (in methyl alcohol) is added in quantities of 1 c.c. at intervals of 10 mins., until 5 c.c. in all has been added; after 1 hr. the precipitate of dixanthylurea is collected on a tared filter, washed with a small quantity of 95% alcohol, dried at 100° C., and weighed. The weight is divided by 7 to obtain the amount of urea. Other substances (e.g., proteins, sugars, uric acid, etc.) occurring in urine do not interfere. The method may be applied to the determination of urea in blood after this has been treated with a mixture of mercuric chloride, 27, potassium iodide 7.2 g., glacial acetic acid 66, and water 100 c.c., and filtered.—W. P. S.

Chlorocarbonic esters. G. Capelli. *Gaz. Chim. Ital.*, 1920, 50, ii., 8—12.

THESE esters may be prepared in 90% yield by the

following procedure. The phosgene supply is connected, through a washing vessel containing vaseline oil to indicate the rate of flow of the gas, with a 5-l. vessel which acts as a safety vessel and for the condensation of any carbon tetrachloride in the phosgene. This vessel is joined to a 5-l. Woulff's bottle, to which are fitted a graduated funnel containing the alcohol to be esterified and a double surface condenser connected with a draught. The vessels may be joined with short pieces of glass tubing for small preparations, otherwise lead tubing should be used; the joints are best made with thoroughly waxed corks. The reaction vessel is charged with 200 g. of well-dried furnace coke in pieces the size of peas and is immersed in pounded ice, the water forming being removed and replaced by fresh ice. After about 30 mins. phosgene is introduced in a steady stream and is absorbed in considerable amount by the coke, the rate of flow being increased after 20 mins. and the alcohol allowed to fall rapidly in drops. 1 kg. of alcohol may be esterified in 4–5 hrs. After standing in a draught for 20 hrs. to ensure the esterification of all the alcohol and to allow the excess of phosgene to escape, the crude ester is washed with water and ice, dried over calcium chloride and fractionally distilled. The alcohol used need not be absolute, 75% alcohol giving good results. The addition of basic substances is of no advantage.

T. H. P.

Chlorhydrins; Formation of —. L. Smith and E. Sammelsson. *Z. physik. Chem.*, 1920, 94, 691–722.

A 40% yield of perfectly pure α -glycerol monochlorhydrin may be obtained by passing hydrogen chloride into 1 g.-mol. of dry glycerol containing 4 g. of succinic acid at 18° C. until the weight has increased 36 g. The addition of hydrogen chloride should take place in two stages with a pause of a day between them. The best laboratory method for the preparation of an approximately pure (1% β isomer) α -chlorhydrin is to add hydrogen chloride to 1 g.-mol. of glycerol containing 4 g. of succinic acid until the weight has increased 47 g.; the heat of the reaction keeps the temperature at 60°–70° C. After the addition is completed the mixture is kept at the ordinary temperature for a day. If there is no special need for a uniform product, a yield of 65% can be obtained by passing hydrogen chloride into the above mixture at 120° C. until the weight has increased 39 g. (*Cf. J.C.S., Oct.*)—J. F. S.

β -Monochlorhydrin; Glycerol —. L. Smith. *Z. physik. Chem.*, 1920, 94, 723–738.

A mixture of 97 g. of glycerol (95%) and 150 g. of hydrochloric acid is heated at 120° C. for 5 hrs., the mixture is distilled at 15 mm. pressure, and the fraction distilling at 110°–150° C. collected. This is pure chlorhydrin containing 15% of the β -isomer. The mixture is fractionated with a rod and disc still-head under a pressure of 11–15 mm. and after many repetitions the pure β -compound obtained. It has b.p. 124.5°–125° C. at 14.5 mm., sp. gr. 1.3375 at 0°, 1.3207 at 20° C.—J. F. S.

"Cupferron"; Preparation of —. D. R. Kasanof. *J. Ind. Eng. Chem.*, 1920, 12, 799.

In the preparation of "cupferron" (J., 1911, 1090) the yield of the intermediate substance, phenylhydroxylamine, depends greatly on the quality of the zinc dust used to reduce the nitrobenzene, but consistently good yields may be obtained by using amalgamated zinc dust. The latter is prepared, immediately before use, by stirring zinc dust with 2% mercurous nitrate solution containing a few c.c. of nitric acid; after a few mins., the solution is decanted and the zinc dust washed with water.

—W. P. S.

Acetone; Estimation of —, in minute amounts, by titration. R. S. Hubbard. *J. Biol. Chem.*, 1920, 43, 43–56.

THE author has modified Messinger's process (J., 1889, 138) so as to make it applicable to the analysis of very dilute acetone solutions. A process of repeated distillation is described whereby acetone may be separated from comparatively large amounts of alcohol and other substances which interfere with the accuracy of the method.

—J. C. D.

Acetone in expired air; Estimation of —. R. S. Hubbard. *J. Biol. Chem.*, 1920, 43, 57–65.

THE air is passed through wash vessels containing sodium bisulphite which effectively holds back all acetone. Interfering substances are removed by a distillation process (*cf. preceding abstract*), and the residual acetone is estimated either by the Scott-Wilson reagent or by titration.—J. C. D.

Copper; Catalytic activity of — [*on oxidation of alcohols*]. I. W. G. Palmer. *Proc. Roy. Soc.*, 1920, A, 98, 13–26.

ELECTROLYTIC copper has no catalytic effect on the oxidation of ethyl or isopropyl alcohol, even when the metal is alloyed with zinc. Copper prepared by the reduction of the oxide catalyses the reaction with the formation of acetaldehyde or acetone. (*Cf. J.C.S., Oct.*)—J. F. S.

Artemisia glutinosa; Essential oil of —. C. T. Bennett. *Perf. Essent. Oil Rec.*, 1920, 11, 286.

THE essential oil of *Artemisia glutinosa*, produced in Spain, has the following characteristics: Odour fragrant and aromatic, recalling that of a mixture of sage, rosemary, and spike lavender, the odour of borneol predominating; sp. gr., 0.937; rotation, +24°; n_D^{20} , 1.4780; total alcohols as borneol, 17.5%; esters as bornyl acetate, 6.3%; phenols, 8%; aldehydes and ketones, 18%; distillation, 52% between 175° and 200° C. The phenol is probably methylchavicol. The presence of thujone could not be established, but a small quantity of a fragrant aldehyde was isolated.—G. F. M.

Recovery of alcohol etc. Mariller. *See XVIII.*

PATENTS.

Esters; Continuous process for the manufacture of —. U.S. Industrial Alcohol Co., Assees. of A. A. Backhaus. E.P. 130,968, 23.6.19. Conv., 7.8.18.

SULPHURIC acid (0.33 pt. by weight of 62–95%), vinegar (10 pts. of 8% acetic acid), and methyl alcohol (0.8 pt. of 95%) are fed continuously into a column still at points situated respectively at the top, near the top, and near the bottom of the still, which is heated at the lower end by a steam coil. Dilute sulphuric acid passes out at the bottom of the still, and a mixture of methyl alcohol and methyl acetate vapour passes out at the top into a dephlegmator, which returns a portion of the alcohol to the top of the still. The remaining vapour passes into the middle of another similar column still; methyl alcohol flows out at the bottom and is led back into the first still at a point opposite the main methyl alcohol supply, and methyl acetate vapour passes out at the top into a dephlegmator, which removes the remaining methyl alcohol and returns it to the top of the still, and thence into a condenser. If glacial acetic acid is used instead of the dilute acid, the ingredients are mixed together and led into the first still through a common delivery pipe. Other acids and alcohols, e.g., formic acid and ethyl alcohol, may be employed.—L. A. C.

Alkaloids; Isolation of —. Chem. Fabr. vorm. Sandoz. E.P. 134,197, 16.8.19. Conv., 25.10.18. Addn. to 125,396 (J., 1920, 349 A).

THE process described in the chief patent and E.P. 131,283 (J., 1920, 426 A) for the extraction of ergot and hyoscyamine may be employed for the extraction of other alkaloids (pilocarpine, aconitine, and yohimbine) from alkaloidal vegetable matter, and also for the extraction of alkaloids from galenical extracts, inspissated juices, or other commercial preparations, in which case vegetable cellular matter such as powdered leaf which has previously been extracted with alcohol and benzene is mixed with the material before treatment.—L. A. C.

Calcium oxalate; Process for making —. F. M. Dupont and G. A. Hanke. U.S.P. 1,319,947, 17.8.20. Appl., 18.3.19.

A MIXTURE of sodium oxalate in solution and suspension, milk of lime, and carbon monoxide is subjected to heat and pressure.—W. J. W.

Caffeine; Manufacture of —. R. L. Datta. U.S.P. 1,350,092, 17.8.20. Appl., 17.10.19.

IN the production of caffeine from tea extract, a portion of the tannin and albumin is precipitated by addition of milk of lime, and the remainder is precipitated by means of basic or normal lead acetate.—L. A. C.

Propylene and its homologues; Preparation of —. Chem. Fabr. Buckau. G.P. 291,794, 6.12.12.

A MIXTURE of acetylene and methane and/or their homologues is passed under high pressure over a suitable porous non-metallic contact substance at 200°–350° C. Suitable catalysts are titanite or silicic acid and their salts, molybdic acid, tungstic acid, thoria, zirconia, etc. Examples are given of the preparation of propylene from acetylene and methane, ethylethylene from acetylene and ethane, and dimethylethylene from allylene and methane.—G. F. M.

Calamus root; Extraction of useful substances from —. A. Deppe Söhne, and O. Zeitschel. G.P. 307,623, 5.8.17.

DRIED and powdered calamus root is extracted with an organic solvent, and the essential oil separated from the fats in this extract by distillation. The residue containing starch and protein is saccharified and fermented for production of alcohol. About 30% of essential oil and 5% of fatty oil are obtained.—W. J. W.

Hydrastinine; Preparation of derivatives of —. K. W. Rosenmund. G.P. 320,480, 6.12.13.

METHYLENEDIOXYPHENYLISOPROPYLAMINE is treated with formaldehyde, or a substance yielding formaldehyde, and a catalyst, and the resulting condensation product is oxidised; or the condensation product is isomerised by means of a catalyst, alkylated, and the product oxidised. Iodine is used as the oxidising agent. For the preparation of 3-methyl-6,7-methylenedioxytetrahydroisoquinoline (m.p. 65°–67° C.) the product obtained from the calculated quantity of methylenedioxyphenylisopropylamine and formaldehyde is heated at 100° C. with 25% hydrochloric acid. The base gives with methyl-iodide 3-methyldihydrohydrastinine hydriodide, m.p. 240° C. The corresponding hydrochloride, m.p. 230° C., is obtained directly by heating the hydrochloride of the isopropylamine derivative with 2 pts. of formaldehyde solution for 3 hrs. at 130°–135° C. On oxidation with alcoholic solution of iodine in presence of potassium acetate, 3-methyldihydrohydrastinine gives 3-methylhydrastinine hydriodide, m.p. 207° C. The free base melts at 103°–104° C. These products are less poisonous than hydrastinine.—G. F. M.

Medicaments for "avitaminosis"; Preparation of —. R. Bosshard and F. Hefti. G.P. 320,785, 19.3.16.

PROTEIN substances rich in vitamins, particularly yeast or rice bran, are treated with dilute mineral acids at 80° C. until the biuret reaction gives a negative result. The product is filtered, freed from mineral acid, and then evaporated to dryness at the lowest possible temperature, either without further treatment, or after the conversion of the amino-acids present into their calcium or sodium salts. By avoiding too high a temperature or acid concentration the vitamins are by this means brought unchanged into solution.—G. F. M.

***o*-Gurtholmanomethyltri-hydroxyarsenomenthol; Preparation of** —. A. Mauersberger. G.P. 320,797, 12.9.15.

MENTHOLGUETHOLSULPHURIC acid ester, a brown, oily liquid, is condensed with monomethylsodium arsenate, or sodium benzenedisulphonate is treated with sodium ethoxide, sodium arsenate is added to the product, and the resulting compound is treated with mentholsulphuric acid methyl ester. The final product is a glutinous mass which solidifies at about 22° C., and has b.p. 154° C. (decomp.).

—L. A. C.

Nitrogenous compounds from the Corpus luteum; Preparation of —. L. Seitz and H. Wintz. G.P. 320,857, 19.7.14.

THE freshly-peeled *Corpora lutea*, reduced to small pieces, are subjected to successive extractions with alcohol and acetone on the one hand, and ether and chloroform on the other. The evaporated acetone extract is mixed with the alcoholic extract and the mixture united with chloroform extract, if necessary with the addition of a further quantity of chloroform. Finally the two layers, which are formed, are separated and evaporated to dryness. Two substances having antagonistic actions are obtained; the one, which is a lipid, soluble in chloroform and containing 61.2% C, 12.5% H, 4.33% N, 2.29% S, 2.83% P, and 16.85% O, stops menstruation, whilst the other, a water-soluble lecithalbumin, promotes menstruation.—G. F. M.

Aldehydes and ketones; Preparation of —. C. Harries. G.P. 321,567, 13.6.18.

REDUCTION of ozonides by means of potassium ferrocyanide, with or without the addition of an acid, yields aldehydes and ketones with little or no resin formation. A 95% yield of vanillin is obtained by reducing isoeugenolozonide in acetic acid, and nonyl aldehyde is formed from *n*-oleic acid ozonide. The ozonides from tar-oil, Hallenser gas-oil, or unsaturated oils which have been prepared by chlorinating crude paraffin oils and splitting off hydrogen chloride form aldehydes and ketones and only a small percentage of acids.—L. A. C.

Cholic acid; Method of obtaining — from bile. H. Wieland. G.P. 321,699, 10.8.16.

BILE is saponified by boiling with sodium hydroxide for 12 hrs., with removal by evaporation of about $\frac{1}{2}$ of the water, and the solution when cold is slowly acidified while being vigorously agitated with petroleum ether to dissolve fatty acids. The crystalline crude cholic acid when boiled with ether yields about 60% of almost pure cholic acid.

—L. A. C.

Mercury compounds of hydroxybenzenesulphocarboxylic acids and their homologues; Preparation of — which form colloidal solutions in water. Saccharin-Fabr. A.-G. vorm. Fahlberg, List und Co. G.P. 321,700, 8.12.18.

THE desired compounds are formed by mixing

aqueous solutions of a hydroxybenzenesulphocarboxylic acid or a homologue and a mercury salt, or by acting upon 1 mol. of a benzenesulphocarboxylic acid with less than $1\frac{1}{2}$ mols. of mercury oxide in the presence of water, and heating the mixtures or allowing them to stand for some time. Alternatively, a mercury compound of a hydroxybenzenesulphocarboxylic acid slightly soluble or insoluble in water is heated with an acid, or compounds or mixtures of mercury and salicylic acid, or its homologues, are treated with sulphuric acid and subsequently heated or allowed to stand for some time in the presence of a dilute acid. Mercury sulphosalicylate (prepared from 5-sulpho-2-hydroxybenzene-1-sulphonic acid) and mercury sulpho-*m*-cresotic acid are white crystalline compounds insoluble in organic solvents but soluble in water forming viscous colloidal solutions.—L. A. C. *Solvent*. G.P. 320,807. See XIII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[*Photographic*] *tone reproduction; Theory of — with a graphic method for the solution of problems*. L. A. Jones. Communication No. 88 from Eastman Kodak Research Lab. J. Franklin Inst., 1920, 190, 39—90.

THE relationship between the appearance of a photographic print and that of the object represented by it is dependent not only on the qualities (characteristic curves) of the negative and positive materials used in making the reproduction, but also upon the conditions of observation, the chief factor in this respect being the variation of the sensitiveness of the eye to brightness variation with varying degrees of illumination. The various factors are considered in detail, a new system of terminology and symbols being used, and a graphic method of combining curves given for investigation of various relationships when certain of the factors are known.—B. V. S.

PATENTS.

[*Photographic*] *colour-filter negative and process of preparing the same*. J. A. H. Hatt. U.S.P. 1,349,956, 17.8.20. Appl., 28.12.18.

A FIRST negative is prepared by exposure through a suitable colour-filter and a second negative by exposure through a different colour-filter and through the first negative in contact with the sensitive surface and in registration with the image of the picture. The second negative is used for the preparation of the printing plate.—B. V. S.

Celluloid products [photographic films]; Process for treating [recovering silver from] —. F. W. Horton. U.S.P. 1,350,157, 17.8.20. Appl., 13.1.20.

FOR the recovery of silver from photographic films they are treated with a solution of caustic alkali and the metal precipitated from the resulting solution.—B. V. S.

Photographic films; Process of making —. E. M. Flaherty, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,350,274, 17.8.20. Appl., 5.12.18.

A SOLUTION of nitrocellulose and camphor in butyl acetate and a diluent is fed on to a revolving drum on which it is partly dried, and the resulting film then stripped off, dried, and reeled in a continuous operation.—B. V. S.

Ferroprussiate paper; Manufacture of —. E. Bertsch. G.P. 320,981, 6.7.18.

ABOUT 10—20% of an alkali oxalate is added to alkali ferric oxalate solution before treatment with ferrieyanide. The yellow product remains unchanged in the dark, and on exposure to light

changes to emerald green, greenish-blue, bright blue-green, yellow, grey, and finally bright yellowish-grey. The treated paper has an intense blue colour after washing and drying, the lines being white.—W. J. W.

Photographic developing process. G. W. A. Sosna and J. E. Biedebach. E.P. 11,036, 29.7.15.

XXII.—EXPLOSIVES; MATCHES.

Nitro explosives; Modern high —. C. F. van Duin and B. C. R. van Lennep. Rec. Trav. Chem., 1920, 39, 145—177.

NITRO compounds of different types, capable of being used as explosives, were examined with respect to their stability, temperature of explosion, and sensitiveness to shock, an endeavour being made to determine the influence of constitution on these properties. In general the 2.3.4.6-tetranitro derivatives decomposed rapidly either at high temperatures or at the ordinary temperature, this being due probably to the splitting off of the nitro group in position 3. A comparison of tetranitroaniline and tetranitrophenylmethylnitramine, the latter being less stable, indicates that the substance containing the most active nitro group is the least stable. The instability of substances with mobile nitro groups is due to these mobile groups, as is shown by the fact that dipicrylamine is stable, whilst 2.4.6.2'.3'.4'-hexanitrodiphenylamine is not; a methylnitramine group also exerts an unfavourable influence on the stability of a compound, but less than the mobile nitro group. The introduction of a fourth nitro group or of a methylnitramine group considerably increases the sensitiveness of a compound to mechanical shock, whilst the introduction of an amino group lowers it. Etherification of a phenol diminishes its sensitiveness. In determining the explosion temperature it is advisable to take two readings, one where the temperature is raised from 100° C. by 20° per minute and the other where it is only raised 5° per minute. There is apparently no definite relationship between the stability of an explosive and the explosion temperature. Where a substance decomposes at its melting-point, this temperature and its explosion temperature are generally almost identical. For testing explosives for their sensitiveness to shock the authors consider that Kast's method (this J., 1909, 47) is quite satisfactory.—W. G.

PATENTS.

Propellant explosive. O. Silberrad. U.S.P. 1,349,983, 17.8.20. Appl., 10.9.19.

A "FLAMELESS powder" consists of nitrocellulose, 30.7%; nitroglycerin, 41%; vaseline, 3.9%; and starch, 21.4%.—W. J. W.

Explosives and other materials; Process for gelatinising —. A.-G. Siegener Dynamit-Fabrik. G.P. 298,420, 14.3.16.

WARM nitroglycerin is forced by compressed air through a jet, and the issuing stream draws in and mixes with air and collodion wool which has been whirled up into dust.—G. F. M.

Nitrocellulose; Process for safely drying — before gelatinisation. C. Claessen. G.P. 298,565, 14.9.16.

NITROCELLULOSE is mixed, in hot water under air agitation, with not more than 6% of a gelatinising aromatic nitro-compound. It then undergoes a preliminary gelatinisation by pressing it between hot plates into slabs which may be easily dried.—W. J. W.

Trinitrotoluene and other aromatic nitro-compounds; Purification of —. Sprengstoff A.-G. Carbonit. G.P. 299,015, 31.10.13.

THE nitro-compounds may be purified by re-

crystallisation from trichloroethylene or tetrachloroethane. Trinitrotoluene is soluble in 2 pts. of the former.—W. J. W.

Trinitrotoluene; Manufacture of —. R. Polltzer and V. Jelocnik. G.P. 299,661, 19.3.15.

PART of the waste acids derived from the manufacture of trinitrotoluene is revivified with nitric acid, and then used for converting mononitrotoluene into dinitrotoluene, part of the waste acid resulting from this operation being utilised for the manufacture of mononitrotoluene. The remainder of the waste acids from both trinitro- and dinitrotoluene manufacture is utilised for nitration of toluene, being thus freed from nitric acid and dissolved nitro-compounds, and the sulphuric acid in the waste acid from the toluene nitration, after purification and concentration, is available for use in the mixed acid for conversion of dinitrotoluene into trinitrotoluene.—W. J. W.

Explosive. A. Wilhelm. G.P. 300,010, 14.3.15. COTMARONE products, alone or mixed with nitrogen compounds, are suitable as vehicles for liquid oxygen or air for use as explosives. The velocity of detonation and brisance are greater than when natural resins are employed.—W. J. W.

Azides of the heavy metals; Preparation of —. O. Matter. G.P. 310,090, 26.8.17.

AN aqueous solution of hydrazoic acid or a metallic azide is added gradually to a solution of the acetate of a heavy metal. The corresponding azide slowly crystallises in fine regular crystals, which can easily be manipulated and will bear pressures up to 15,000 kg. per sq. cm. without exploding.

—G. F. M.

Picric acid; Manufacture of —. L. G. Badier and L. B. Holliday, Assrs. to L. B. Holliday and Co., Ltd. U.S.P. 1,349,802, 17.8.20. Appl., 30.12.19.

SEE E.P. 9962 of 1915; J., 1919, 305A.

[*Picric acid;*] *Evaporator [for concentrating weak solutions of —]*. J. N. Brooke. U.S.P. 1,349,810, 17.8.20. Appl., 1.7.18.

SEE E.P. 120,951 of 1917; J., 1919, 92A.

XXIII. — ANALYSIS.

Thermocouple for low temperature work; Needle type —. G. F. Taylor. J. Ind. Eng. Chem., 1920, 12, 797—798.

A METHOD of making this kind of thermocouple is described. Silk-insulated copper and "constantan" wires are used; as many lengths (about 1 m.) of each as there are to be junctions (*e.g.*, 1 to 50, or more) are cut, gathered together, and each end of the bundle is slipped through a hard glass tube, the ends of the wires are dipped in "bakelite," the insulation burned away for a length of 1 cm., the ends are twisted together in pairs and soldered. Each junction is then insulated by fusing over it a very small glass tube, and a tube of copper foil, 5 mm. in length, is drawn over the bundle above the junctions so that one end extends within the glass tube. The other end of the couple is made in the same way. A ten-junction thermocouple of No. 36 B. and S. gauge wire is only 1.5 mm. in diameter; it has a value of 0.002169° C. per microvolt over a range of 0° to -2° with a lag of 0.76 sec.—W. P. S.

Specific gravities; Determination of — by the pycnometer. W. Block. Z. angew. Chem., 1920, 33, 198—200.

THE author discusses the determination of sp. gr.

by means of the pycnometer and indicates the precautions to be observed as regards temperature, weighing, influence of atmospheric pressure, etc.

—W. P. S.

Specific gravity; The viscosimeter as a means of determining —. J. Holker. J. Path. Bact., 1920, 23, 185—187.

By combining the formulae of Ostwald-Poiseuille and of Scarpa (J., 1911, 51), in which the specific gravity of the liquid does, and does not, occur, respectively, it is possible to find the specific gravity by the viscosimeter. The results were in satisfactory agreement, and 2 c.c. or less of liquid is sufficient.—J. R. P.

Viscosities; Method of determining several — simultaneously. J. Holker. J. Path. Bact., 1920, 23, 177—184.

THE method of Scarpa (*cf.* preceding abstract) has been modified, and a method devised for determining several viscosities simultaneously. The method depends on the measurement of two times, t_1 and t_2 , the former occupied in drawing up through a vertical capillary sufficient liquid to fill a bulb at the top of this tube, and the latter taken by the liquid in flowing out of the bulb under its own weight. Under constant conditions, the viscosity is then proportional to $t_1 t_2 / (t_1 + t_2)$.

—J. R. P.

Calorimeter; Electrical adiabatic —. E. Cohen and A. L. T. Moesveld. Z. physik. Chem., 1920, 95, 305—327.

AN adiabatic calorimeter is described on the principle of that used by Richards, the main difference consisting in heating the liquid in the surrounding jacket by an electric current instead of by the neutralisation of sodium hydroxide by acid.—J. F. S.

Boiling point determinations under reduced pressure; Little noted sources of error in —. C. von Rechenberg and E. Brauer. Z. physik. Chem., 1920, 95, 184—214.

BOILING point determinations under reduced pressure are best carried out by the dynamic method. The following conditions should be observed: the boiling flask may be of glass or metal; in the latter case a flattened bottom is preferable, whilst in the case of glass a second neck carrying a capillary tube is advantageous. The neck of the flask should be surrounded with a vapour mantle; the boiling tube should be at least 20 mm. wide, the neck and condenser tubes 15 mm. wide. The thermometer bulb should be placed at least 50 mm. above the level of the boiling liquid, and the whole of the mercury thread should be in the vapour. Pressure measurements should be made on the boiling tube. The manometer should have a tube 15 mm. wide and be vertical. Pressures below 5 mm. should not be measured in this way, and the velocity of distillation should never be greater than one drop per second. Temperature and pressure measurements should not be made until 10 c.c. has distilled over. (*Cf.* J.C.S., Oct.)

—J. F. S.

Alundum filtering crucibles; Use of —. D. T. Inglis. J. Ind. Eng. Chem., 1920, 12, 799—800.

AFTER a precipitate in an alundum crucible has been washed as completely as possible in the usual way, it sometimes happens that soluble salts are retained by the upper portion of the crucible; these may be removed by placing the crucible in a suitable support in an ordinary funnel, pressing a moistened rubber stopper over the top of the crucible, applying suction, and pouring water into the funnel.—W. P. S.

Membrane filters; Chemical analysis with —. L. Moser and Kittl. Chem.-Zeit., 1920, 44, 637—638.

ALTHOUGH membrane filters are very useful for the separation of colloidal precipitates from liquids, their application to quantitative analysis, as recommended by Zsigmondy and Jander (J., 1919, 928A) is limited. The precipitate penetrates the surface of the membrane to a slight extent so that the whole of the precipitate cannot be removed for weighing, and it is not practicable to ignite the precipitate and membrane filter together.

—W. P. S.

Litmus paper; Preparation of red —. W. Fresenius and L. Grünhut. Z. anal. Chem., 1920, 59, 233—234.

ONE hundred g. of powdered litmus is boiled for 15 mins. with 500 c.c. of 94% alcohol, the mixture filtered, the insoluble portion dried at 100° C., and then ground with 500 c.c. of cold water; this mixture is stirred occasionally during 24 hrs., filtered, and a portion of the filtrate is set aside whilst the main portion is treated with dilute sulphuric acid (sp. gr. 1.11) until the colour changes to red. The solution is boiled for 15 mins., evaporated water being replaced, and, if the colour changes to blue, a trace more acid is added. A strip of paper is then dipped in the solution and dried. If too much acid has been used a quantity of the reserved portion of the filtrate may be added. When the desired tint after drying has been obtained, strips of paper are dipped in the solution and dried in an atmosphere free from acids and ammonia. Litmus paper thus prepared should give a blue coloration when treated with a drop of a mixture of 50 c.c. of boiling water and 1 drop of N/4 alkali solution.—W. P. S.

Alkalimetric titrations; Influence of atmospheric carbon dioxide on — using phenolphthalein as indicator. G. Bruhns. Z. Zuckerind. Czechoslov., 1920, 44, 331—335.

WHEN approximately N/100 sodium hydroxide solution is titrated with N/100 hydrochloric acid, using phenolphthalein as indicator, less of the acid is required than is the case with methyl orange as indicator. The difference may amount to about 10% of the volume of acid used, and is due to the absorption of carbon dioxide from the atmosphere during the titration. This influence of carbon dioxide is of importance in the determination of the alkalinity of sugar syrups; it may be diminished by reversing the procedure and adding the alkali solution to the acid.—W. P. S.

Water; Preparation of ammonia-free — [for analytical purposes]. G. C. Baker. J. Ind. Eng. Chem., 1920, 12, 798—799.

DISTILLED water is passed downwards through a layer of permutite, 12 in. deep and about 8 in. in diameter; this quantity of permutite will remove all the free ammonia from 100 gals. of water, but increases the mineral matter content. The activity of the permutite may be regenerated by treatment with 10% sodium chloride solution and washing as usual.—W. P. S.

Copper; Rapid determination of small amounts of — by the iodide method. H. F. Bradley. J. Ind. Eng. Chem., 1920, 12, 800.

THE precipitate of cupric sulphide, containing not more than 0.05 g. of Cu, is washed until free from chloride (complete removal of iron is not necessary), moistened with a few drops of zinc nitrate solution, and ignited; the residue of oxides is dissolved by warming with 1 c.c. of dilute hydrochloric acid (1:2), the solution neutralised with 5% potassium hydroxide solution, acidified with acetic acid, treated with a small quantity of phosphate solu-

tion to prevent interference by iron, 2.5 g. of sodium iodide added, and the liberated iodine titrated.—W. P. S.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

- Baumgartner. Filtering media for liquids. 27,123. Sep. 23. (Austria, 6.11.15.)
 Biancardi. 26,986. See XIX.
 Conder and Vivian. Crushing machines. 26,623. Sep. 17.
 Hargreave. Apparatus for drying, concentrating, and filming solids, liquids, etc. 26,214. Sep. 13.
 Hayhurst. Filtering apparatus. 27,258. Sep. 24.
 Hayhurst. Liquid evaporators. 27,259. Sep. 24.
 Hofmann. Apparatus for drying pulverulent etc. substances. 26,657. Sep. 17.
 Metcalfe. Continuous kilns of the tunnel type. 26,556. Sep. 16.
 Noeggerath. Pumping or propelling semi-solids by viscosity pumps. 26,557. Sep. 16.
 Smallwood. Furnaces. 26,219. Sep. 13.
 Speight. Drying-cylinders, calenders, etc. 26,313. Sep. 14.
 Topf n. Söhne, and Wettig. Drying apparatus. 26,941. Sep. 21.
 Tregoning and Vivian. Grinding machinery. 26,397. Sep. 15.
 Walker. Pulverising mills. 26,358. Sep. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

- 8571 (1919). Anderson. Furnaces or kilns. (150,762.) Sep. 22.
 14,097 (1919). Merz. Apparatus for evaporating liquids or recovering gases or vapours developed therefrom. (150,785.) Sep. 22.
 14,093 (1919). Merz. Extracting water from materials. (150,786.) Sep. 22.
 14,405 (1919). Thompson (Union Espagnole de Fabr. d'Engrais de Prod. Chim. et de Superphosphates). Centrifugal pumps, especially for acids etc. (127,831.) Sep. 22.
 14,888 (1919). Aube. Pulverising apparatus. (151,072.) Sep. 29.
 3333 (1920). Jewell. Stills. (150,940.) Sep. 22.
 8340 (1920). Akt. Myrens Verksted. Apparatus for drying moist solids. (140,473.) Sep. 22.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- American Coke and Chemical Co. Coke ovens etc. 26,667. Sep. 17. (U.S., 3,10,19.)
 Davidson. 26,276. *See* XXIII.
 Davis and others. 27,157. *See* XXIII.
 George. Decomposing heavy hydrocarbon oils into lighter oils. 26,340. Sep. 14. (U.S., 30,9,19.)
 Hamer. Removal of water from oil. 27,216. Sep. 24.
 Herbert. Fuels for internal-combustion engines. 27,203. Sep. 24.
 Holst, Oosterhuis, and N. V. Philips Gloeilampenfabr. Removing gas residues and purifying inert gases in electric vacuum tubes. 26,994. Sep. 22. (Holland, 23,9,19.)
 Hutchins. Apparatus for destructive distillation of carbonaceous materials. 26,448. Sep. 15.
 Lessing. Treatment of coal. 27,162. Sep. 23.
 Pick and Strafford. Manufacture of solid fuel and distillation of tar. 26,568. Sep. 16.
 Soc. Franco-Belge de Fours à Coke. Treatment of gases from gas-producers. 26,451. Sep. 15. (Belg., 11,3,20.)
 Thompson (Gish). Treating hydrocarbons for explosive engines. 26,405. Sep. 15.
 Wallace. Apparatus for distilling carbonaceous materials. 27,278. Sep. 24.
 Wallace. Carbonising carbonaceous materials. 27,279. Sep. 24.
 White (Arrowood). Preparing powdered fuel for combustion. 27,028. Sep. 22.
 Wilputto. Coke-ovens etc. 26,789, 27,023, 27,038, 27,046. Sep. 20 and 22.
 Zwillingler. Coke-ovens. 26,461. Sep. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

- 14,121 (1919). Lynn and Rambush. Generation and utilisation of producer gas. (150,787.) Sep. 22.
 32,709 (1919). Andre. Recovery of combustible material from furnace and boiler ashes. (151,192.) Sep. 29.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

- Atack. Process for oxidising hydrocarbons. 26,698. Sep. 18.
 Pick and Strafford. 26,568. *See* II.

COMPLETE SPECIFICATION ACCEPTED.

- 11,439 (1919). Dayton Metal Products Co. Hydrogenation of benzene. (133,666.) Sep. 22.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Donington. 26,542. *See* XVII.
 Dreyfus. Manufacture or treatment of products made with cellulose derivatives. 26,733. Sep. 18.
 Great Northern Paper Co. Paper-making. 27,169. Sep. 23. (U.S., 28,3,19.)
 Roerig. Manufacture of acetylcellulose. 27,158. Sep. 23.
 Soc. d'Impression des Vosges et de Normandie. Production of cotton goods to imitate wool or silk with a moiré effect. 26,821. Sep. 20. (Fr., 18,9,19.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 5596 (1919). Kirschbraun. Manufacture of waterproof paper or felted sheets. (151,029.) Sep. 29.
 14,028 (1919). Milne. Stationary digesters etc. used in paper-making etc. (150,782.) Sep. 22.

- 19,802 (1919). Clayton. Apparatus used in making artificial silk. (150,889.) Sep. 22.
 20,156 (1919). Johnson. Process for retting flax. (151,143.) Sep. 29.
 1125 (1920). Great Northern Paper Co. Paper-making. (137,815.) Sep. 29.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

- Brandwood, Pearce, and Sherwood. Cop-dyeing machines. 27,301. Sep. 25.
 Poulson. Sizing textile fabrics etc. 27,197-8. Sep. 24.

COMPLETE SPECIFICATION ACCEPTED.

- 11,231 (1919). Calico Printers' Assoc., and Rouse. Printing cotton fabrics. (151,056.) Sep. 29.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- A.-G. f. Stickstoffdünger. Manufacture of nitrocalcite capable of being sprinkled and stored. 26,269. Sep. 13. (Ger., 12,9,19.)
 Bacon (Oldbury Electro-Chemical Co.). Manufacture of alkali formates and oxalates. 26,661-3. Sep. 17.
 Commin. Apparatus for producing cyanogen compounds or cyanides. 27,015. Sep. 22.
 Johnson (Badische Anilin u. Soda Fabr.). Manufacture of hydrochloric acid. 27,122. Sep. 23.
 Lunden and Thorssell. Production of ammonia from cyanides. 26,677-8. Sep. 19. (Sweden, 6,10,19.)
 Reed. Manufacture of sulphuric acid. 26,802. Sep. 20.
 Roiboul. 26,357 and 27,183. *See* VIII.
 Soc. Anon. l'Azote Français. Recovery of nitrous vapours. 27,161. Sep. 23. (Switz., 5,7,20.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 15,205 (1919). British Thomson-Houston Co. (General Electric Co.). Manufacture of nitric acid. (150,836.) Sep. 22.
 15,561 (1919). Thorssell and Lunden. Production of cyanides. (151,098.) Sep. 29.
 21,040 (1919). Deuts. Molybdänwerke. *See* X.
 24,129 (1919). Burgess Laboratories. Manufacture of zinc chloride. (133,319.) Sep. 29.
 26,740 (1919). Brusa, and Borelli & Co. Apparatus for making mercuric oxide from mercurous nitrate. (150,917.) Sep. 22.

I.—GENERAL; PLANT; MACHINERY.

Evaporator design; Studies in —. III. W. L. Badger and P. W. Shepard. Chem. and Met. Eng., 1920, 23, 390—393. (See J., 1920, 647 A.)

THE effect of hydrostatic head on heat transmission is dealt with, and the following conclusions are arrived at:—When treating water or other non-foaming, non-viscous liquids, heat transmission attains a maximum when the tubes are from one-third to one-half submerged; the shape of the bottom of the evaporator and hence the quantity of liquid below the bottom tube-plate compared with that above influences the result, the greater the amount of this bottom liquid the less being the influence of variation of hydrostatic head. As the liquor head increases above the top tube-plate, the heat transmission falls off along a straight line. These changes are only partly due to the variation of hydrostatic head, as variations in the velocity of circulation have considerable influence on the result.—W. H. C.

Coal-saving in the chemical industry. D. Brownlie. Chem. Trade J., 1920, 67, 247—250, 311—314, 343—347.

SEVERAL tables are given showing the results of tests made of the boiler plants of 60 works engaged in various branches of the chemical industry, together with a description of the methods used and a discussion of the results obtained. The average efficiency was found to be only 58%, and the poor results are attributed to the following causes:—Boiler grates are often too long, and too little fuel is burned per sq. ft. of grate area; the coal is frequently not tested, nor is a continuous record of the evaporation obtained always kept; impure feed water is not always treated, and often too little advantage is taken of the economisers even where they are installed. The measurement of the feed water and of the steam produced, the weighing and analysis of the fuel, and the installation of some form of continuous CO₂ recorder are the means indicated, together with a careful and regular consideration of the figures so obtained, by which an improvement may be effected.—W. H. C.

Ultra-filtration on an industrial scale. G. Schmitt. Chem.-Zeit., 1920, 44, 657—658, 669—671.

A TYPE of filter for the filtration of fine or colloidal suspensions is described, consisting of a perforated metal cylinder surrounded by numerous rings of fine wire gauze, which can be pressed together by means of a screw, so that the size of the filter pores can be regulated during the filtration. A screw conveyor within the cylinder forces the liquid through the filter, the actual filtering medium being a uniform layer of the deposit from the liquid itself. A medium suitable for colloidal filtration is formed by passing fibrous or pulverulent material through the filter. Instead of wire gauze, thin perforated metal rings may be used; or the spaces between the wire gauze rings may be packed with asbestos, cement, plaster of Paris, etc., to form a compact outer cylinder. Filtration is preferably effected at a pressure of 10 atmospheres. In another modification cylindrical cores are wrapped with wire in several places, the liquid then passing through the spaces between these wires, which for certain purposes may be covered with yarn, asbestos, cellulose, etc. These filtering surfaces behave like osmotic membranes, with the additional advantage of strength. For the filtration of large volumes of liquid they may be arranged vertically or horizontally in groups, or they may be used separately as revolving presses, the screw conveyor then being replaced by a central ram. In this way a pressure

of over 300 atm. is obtainable. These presses are particularly suitable for the dehydration of clay for ceramic purposes, for the separation of precipitated pigments, the removal of bacteria from water supplies, separation of organic dyestuffs from the liquids in which they have been formed, and in the varnish and sugar industries. Oil may be simultaneously expressed from oil seeds at high pressure and filtered, and gases freed from suspended matter, with or without electrical precipitation.—C. A. M.

Distillation and rectification. Gay. See XVIII.

PATENTS.

Grinding machines [with air separation]. F. L. Smith & Co. E.P. 127,589, 29.5.19. Conv., 30.5.18.

In the fig. *d* is a fixed grinding ring, *e* grinding balls, and *c* an inner segmental grinding ring driven by the shaft, *a*, and forced against the balls by the

centrifugal force of loading blocks, *f*. The cage, *h*, is merely to separate the balls and is not driven. A disc, *j*, rotating with the shaft, has vanes, *l*, on its underside which draw air through ports, *n*, and force it (together with the ground material) through the narrow space between the outer grinding ring, *d*, and the outer casing. The velocity of the air here is sufficient to lift all the partly ground material, but on arrival at the larger space above the balls the velocity decreases so that the coarser particles fall back to be re-ground, and only the finely-ground material is blown out through *q*.

—B. M. V.

Surface condensers. R. N. Ehrhart. E.P. (A) 131,595, 18.8.19, and (B) 134,852, 6.11.19. Conv., 21.8 and 8.11.18.

(A) A RECTANGULAR condenser shell is provided with a vapour inlet, a condensed liquid discharge, and two outlets for the non-condensable fluid. Two nests of horizontal tubes are disposed within the shell so as to leave a downwardly tapering passage between them. Each nest of tubes is divided by a longitudinal baffle plate into two substantially triangular banks of tubes through which the steam passes in the direction of their decreasing cross-section. (B) The nests of tubes are arranged so as to leave a central converging passage from the vapour inlet to the condensed liquid outlet and to expose two sides of each nest to the incoming condensable fluid. Outlets for the non-condensable gas are provided midway between the top and bottom of each nest of tubes, which is further divided at this level by a substantially horizontal baffle plate, so that part of the condenser wall and a baffle plate form one of several converging passages leading to the non-condensable gas outlets.—W. H. C.

Drying processes in drying plants; Control of —.

G. Crida. E.P. 140,104, 11.3.20. Conv., 11.3.19.

THE substance being dried is supported in a counter-balanced container, the weight being recorded on a chart. Besides indicating, the pointer of the instrument also makes contact with either side of a double flexible conducting strip which is bent into such a position on the chart that the rate of drying at any instant may be maintained according to a pre-determined curve of maximum efficiency. For example, a reversible electric motor controlled by the contact arm may be used to control the heat supply.—B. M. V.

Drying processes and apparatus therefor. T.

Boberg, and Techno-Chemical Laboratories, Ltd. E.P. 149,055, 3.5.19.

THE wet material is spread upon a heated surface (e.g., a rotating drum), to which it is caused to adhere until it is sufficiently dry, when it is removed. The apparatus is enclosed in a casing and the steam given off is withdrawn, and after having its temperature raised by being compressed is utilised as the heating medium.—W. H. C.

Drying processes and apparatus therefor. T.

Boberg, and Techno-Chemical Laboratories, Ltd. E.P. 150,068, 27.5.19.

PULPY material of high water content, e.g., peat, is spread in a thin film on a slowly rotating heated drum or the like, and the vapour given off is compressed to raise its temperature and applied to the interior of the drum to heat it. The partially dried material is scraped off the drum at a suitable point and transferred to another similar dryer. If desired the drying may be effected in three or more stages instead of in two stages.—B. M. V.

Drying apparatus. J. L. Cloudsley. E.P. 149,774, 19.5.19.

AN apparatus for drying such material as broken stone or sand consists of a number of superposed trays, alternately convex and concave, the material flowing down the slope and over the outer edge of the former and down the slope and through a central opening of the latter. The trays are vibrated vertically by means of a central shaft, to which both sets or either set may be rigidly attached; in the latter case the second set is carried by resilient supports. The slope of the convex plates is much flatter near the circumference than near the centre.—B. M. V.

Dryer. J. O. Tensfeldt. U.S.P. 1,349,590, 17.8.20. Appl., 18.11.19.

A DISTRIBUTING system for dry hot air is arranged above a drying chamber, below which is a chamber for receiving the moisture-laden air. The air is withdrawn from this latter chamber, dried, and returned to the distributing system, whence it passes downwards through the material being dried.—W. H. C.

Desiccating fluid substances; Process for —.

R. W. G. Stutzke, Assr. to Crown Maltose Co. U.S.P. 1,350,247, 17.8.20. Appl., 8.6.16.

THE fluid is injected as a spray into a superheated atmosphere of its own vapour, the evaporated liquid is withdrawn from the system at such a rate as to maintain a sub-atmospheric pressure, and the desiccated solids are collected.—J. H. L.

Filtering and/or mixing oils and other liquids;

Apparatus for —. R. H. Cox. E.P. 149,038, 30.4.19.

THE liquid is fed through a hollow shaft into a horizontal drum, the peripheral wall of which is formed of two layers of wire gauze or perforated metal with one or more layers of felt or other suit-

able material between. The drum is rotated at high speed in a tank in which the liquid collects after passing through the gauze and fabric.—W. H. C.

Distilling and fractionating liquids [e.g., petroleum]; Apparatus for —. J. Y. Johnson. From H. L. Allan. E.P. 149,776, 20.5.19.

PETROLEUM or other hydrocarbon is fractionally distilled in a series of rectifiers which are connected at the top by atmospheric condenser and reflux pipes. Each rectifier is provided with a number of vertical open-ended tubes through which the liquid passes upwards from a header at the bottom and overflows at the top into an upper chamber formed by a horizontal partition midway of the height of the rectifier. The liquid then passes through a connecting pipe to the bottom header of the next rectifier. The lower portions of the vertical tubes may pass through a compartment bounded by two horizontal partitions, and superheated steam may be passed into this compartment. The vapour passes into the next rectifier by the air condenser pipes at the top.—W. F. F.

Heated air; Arrangements for supplying — to furnaces. W. H. Owen. E.P. 150,065, 27.5.19.

THE air for combustion is heated by the waste gases: after an initial heating the hot air is divided, part going direct under the fire-bars, the other part being further heated to a much higher temperature and supplied above the fire-bars.—B. M. V.

Kilns. W. Somerville. E.P. 150,157, 23.7.19.

IN a kiln for burning lime, dolomite, etc., outlets for carbon dioxide are provided just below the level of the fuel bed, leading to damper-controlled uptakes, which rejoin the main chimney above the main dampers. The fire is only allowed to burn upwards at starting.—B. M. V.

Foam in liquids; Method of producing —. E. Wirth-Frey. U.S.P. 1,351,089, 31.8.20. Appl., 8.4.19.

DURING the heating of liquids the steam generated is drawn off and re-introduced under pressure, out of contact with the atmosphere, in order to produce foam.—W. J. W.

Separating substances from liquids [e.g., wax from mineral oils]; Process for —. P. T. Sharples. U.S.P. 1,351,265, 31.8.20. Appl., 28.6.19.

TO separate from a liquid a substance which is soluble in it at normal temperatures, but insoluble at lower temperatures, the mixture is cooled to a temperature at which the substance separates, and centrifuged with a liquid which is heavier than the substance and non-miscible with it. The substance floats on the heavier liquid and is separately discharged. The process is applicable to the separation of wax from mineral oils by means of brine.—W. F. F.

Material from solution; Apparatus for recovering —. W. D. Mount, Assr. to Nitrogen Products Co. U.S.P. 1,352,210, 7.9.20. Appl., 27.6.18.

THE solution is heated in a horizontal cylindrical casing provided with a combined agitator and conveyor which can be rotated in one direction to agitate the contents of the casing and in another direction to discharge the material at one end of the casing.—B. V. S.

Fire-extinguishing liquid. S. S. Sadtler, Assr. to C. B. Ford and J. M. Castle. U.S.P. 1,316,191, 16.9.19. Appl., 28.4.17.

CARBON tetrachloride is mixed with less than 10% of a saturated hydrocarbon adapted to lower the freezing point and raise the flash-point of the composition comparatively to the freezing and flash-

points of carbon tetrachloride. One example of such a mixture is carbon tetrachloride with about 5% of petroleum spirit (sp. gr. 0.759–0.766); this mixture has a flash-point of 113.5° C. and a freezing point of 10° C.—W. H. C.

Evaporating apparatus. S. M. Duck. E.P. 150,007, 7.2.19.

Treating liquids. U.S.P. 1,351,522. See XVIII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Lignite; Comparison of methods for producing tar and gas from —. H. Holzwarth. Braunkohle, 1920, 19, 189–192. Chem. Zentr., 1920, 91, IV., 374–375.

Four methods of treatment of lignite containing 8% of bitumen have been compared, viz.: (1) The moist lignite was directly gasified in producers; (2) the lignite in the form of briquettes containing 15% of moisture was gasified with recovery of tar and by-products; (3) partial carbonisation in rotary ovens to obtain tar and burning coke; (4) partial carbonisation in Thyssen rotary ovens for production of burning coke and subsequent gasification of the coke in producers. The following results were obtained, calculated to the raw, undried lignite:—

	1.	2.	3.	4.
Consumption of raw lignite in production of 1 million calories in the gas	700 kz.	1805 kg.	925 kg.	800 kg.
Tar yield in production of 1 million calories in the gas	28 kg.	31 kg.	29.3 kg.	63 kg.
Ratio raw lignite consumed : tar produced	25	5	31.6	12.5

—A. J. H.

Heavy mineral oils; Determination of the specific heat of —. H. S. Bailey and C. B. Edwards. J. Ind. Eng. Chem., 1920, 12, 891–894.

THE oil (250 g.) is introduced into a vacuum-jacketed calorimeter provided with an electrical resistance coil and a stirrer, and a current of measured strength transmitted. The temperature, voltage, and amperage are read at intervals of

1 min. between the limits of temperature required, the current then cut off, and the system allowed to cool with the agitator still running, and the falling temperature noted at intervals of 5–10 mins. through the range. The specific heat is calculated by means of the equation

$$\text{Sp. ht} = C/W = V \times A \times 60 \times 0.239 / W(t + r) + c/W,$$

where C is the heat capacity of the oil, W the weight of oil, V the average voltage, A the average amperage, 0.239 cal. per joule, c is the water equivalent of the calorimeter, t the rise of temperature in ° C. per min., and r the radiation in ° C. per min. from the cooling curve. The specific heat of aniline thus determined agreed closely with the recorded value.—C. A. M.

Coal; Economic selection of —. A. L. Booth. Iron and Steel Inst., Sept., 1920. [Advance proof.] 9 pp.

FOR the selection of a suitable coal for industrial use microscopical examination may be of value when used in conjunction with chemical analysis. The author classes coals in three main types—"humic," "spore," and "cannel" coals (Lomax, Trans. Inst. Mining Eng., 1911, 42, (i.), 1; J., 1913, 276). The extent to which these types merge into one another is judged from the microscopical examination. For steam raising humic coals, containing a fair proportion of cuticle or spores, are the most suitable. Spore coals are necessary for producer-gas work. For direct-fired furnaces the hard coals, which are almost true cannels, are used. Coal from the same seam was found to be usually very uniform, even when delivered on dates several years apart.—W. P.

Gasoline from natural gas. III. Heating value, specific gravity, and specific heat. R. P. Anderson. J. Ind. Eng. Chem., 1920, 12, 852–857.

FORMULÆ are given showing the relationship between the cal. per g.-mol. of normal paraffin hydrocarbons and the number of carbon atoms per mol., and between the B.Th.U. per lb., per cub. ft., and per gall., and the number of carbon atoms per mol. and sp. gr. in liquid form respectively. In so far as gasoline is a mixture of normal paraffin hydrocarbons, the relationship between the B.Th.U. per lb. or per gall. and the sp. gr. (G.) may be expressed by the formulæ—B.Th.U. per lb. = $23,330 - 3500 G$; B.Th.U. per gall. (at 15.5° C.) = $14,200 + 153,500 G$. These formulæ may be applied directly to natural-gas gasoline and straight-run gasoline. The probable values of the heating value and sp. gr. of the vapour and vol. of vapour per gall. have been calculated for four grades of gasoline, and figures are given showing the change in the heating value and sp. gr. caused by the extraction of different amounts of gasoline from different grades of natural gas.

—C. A. M.

Java petroleum; Catalytic hydrogenation of lava-rotatory fractions of —. W. Steinkopf and F. Beiersdorf. J. prakt. Chem., 1920, 101, 75–78.

NO inversion of the sign of rotation was produced by the catalytic hydrogenation of Java petroleum fractions, and the very slight alterations observed in the magnitude of the specific rotation appear to indicate that optical activity is caused by the presence of a saturated compound which is not affected by hydrogenation. The rotation cannot be due to the presence of cholesterylene, since this, when catalytically hydrogenated, yields dextro-rotatory cholestane. The optical activity of the oils is more pronounced as the quantity of unsaturated substances in them diminishes.—H. W.

Asphalt and coke content of petroleum; Relations between the —. W. Steinkopf and H. Winternitz. J. prakt. Chem., 1920, 101, 82–92.

PETROLEUMS with a high content of hard asphalt

give also a high yield of coke. Soft asphalt can, however, play a considerable rôle in the formation of coke, since certain oils which have a particularly small hard asphalt content show a high coke number. About 40–60% of the soft asphalt is converted into coke. The differences between the coke yields determined at the ordinary pressure and in a vacuum are only considerable if the oil has a high asphalt content.—H. W.

Mixtures of gases. Weaver and Palmer. See XXIII.

PATENTS.

Fuel; Manufacture of — and apparatus therefor. J. Armstrong. E.P. 149,449, 20.5.19.

POWDERED fuel, e.g., coal, peat, sawdust, etc., is compressed with a binder to form a long continuous bar, in which deep narrow grooves are cut by revolving blades, running in a bath of tar, oil, water, or other liquid which is thus deposited in the grooves. On combustion the liquid produces vapours which open up the structure of the briquette and thus promote satisfactory combustion.—A. G.

Peat; Method of treating —. W. W. Blair. U.S.P. (A) 1,349,713 and (B) 1,349,714, 17.8.20. Appl., (A) 20.6.18, (B) 14.12.16. (B) Renewed 13.5.19.

(A) FRESHLY dug peat is macerated, pressed into blocks, dried, and impregnated with a fuel-oil. (B) Raw peat (unmacerated) is compressed into blocks, which are dried and impregnated with a fuel-oil.—A. G.

Water-gas; Producing — and carbonising coal. H. L. Doherty. E.P. 132,483, 10.5.19. Conv., 7.9.18.

A COLUMN of fuel is subjected to a cross blast of air to produce a high temperature zone, and a longitudinal blast of steam for the production of water-gas. The current of steam may be started before the cross blast is entirely cut off. The furnace comprises a fuel shaft communicating with regenerators by way of transverse flues opening into the shaft at an intermediate zone, the shaft at this zone being restricted in sectional area and formed (e.g. by arches), so as to deflect the transverse blast downwards between the flue openings. The fire arches are connected by controlled passages for leading a portion of the gas of the transverse blast direct from one flue to the other.—A. G.

Gas producers. S. B. Sheldon. U.S.P. (A) 1,350,472, (B) 1,350,473, (C) 1,350,474, and (D) 1,350,475, 24.8.20. Appl. (A, B) 11.6.18, (C) 6.9.18, (D) 4.11.18.

(A) POKERS are mounted on opposite sides of the centre of a revolving beam, thus disturbing the fuel in the coking zone. (B) Fuel is fed by means of a plunger from the floor of a water-cooled hopper, located directly above the top cover of the producer, on to a water-cooled distributor, actuated externally. (C) The cover of the producer is mounted on wheels and can rotate on a track running round the periphery of the main structure. A superstructure capable of rotation is mounted independently of the top and carries the producer-operating mechanism. (D) The body of the producer is capable of rotation whilst the top is stationary and is sealed to prevent escape of gas. The top has a large number of poker openings and vertical pokers which fit loosely in the openings by ball and socket joints, so as to lag as the body rotates. The ball-and-socket members are pierced so that the poker shanks can move reciprocally. The pokers are raised by actuating mechanism and fall by gravity

at regular intervals, so that the fuel bed is maintained in a porous condition.—A. G.

Acetylene or like explosive gases dissolved in liquids; Porous charges for containers for storage of —. J. Pintsch A.-G. E.P. 135,511, 21.11.19. Conv., 20.5.14.

THE charge consists partly, but not wholly, of porous materials capable of swelling, e.g., cork, elder-pith, or like substances of vegetable origin.—A. G.

Fuel; Process of producing liquid — and product thereof. E. C. R. Marks. From U.S. Industrial Alcohol Co. E.P. 149,398, 7.5.19.

10 g. of calcium carbide is added to 50 c.c. of ethyl alcohol (95%). Part of the acetylene produced by the dehydration of the alcohol dissolves in the alcohol, whilst the balance is passed into a mixture of 50 c.c. of gasoline and 40 c.c. of kerosene. The dehydrated alcohol is filtered off from any calcium hydroxide produced and is then mixed with the gasoline and kerosene, thus producing a liquid suitable for motor fuel or for burners.—A. G.

Wax; Process of expressing — from petroleum distillates. W. C. and F. E. Wells. U.S.P. 1,350,482, 24.8.20. Appl., 23.4.14.

THE distillates are fed to a woollen fabric strainer, uniformly and adequately supported by a structure that does not cause material obstruction, so that, under sufficient pressure, the oils are expressed from the distillate.—A. G.

Gasoline; Process for cleaning —. M. Leitch, Assr. to De Laval Separator Co. U.S.P. 1,351,047, 31.8.20. Appl., 23.9.18.

GASOLINE contaminated with water and other impurities is mixed with a saponifying agent and the resulting emulsion is broken, whereby it separates into a layer of pure gasoline and other layers containing the soap, water, and dirt free from gasoline.—W. F. F.

Volatile [hydrocarbon] liquids from gases; Process for obtaining —. L. F. Bayer. U.S.P. 1,351,151, 31.8.20. Appl., 11.10.17.

THE gas is mixed with a hydrocarbon oil and the mixture compressed. Another liquid is artificially refrigerated and added to the mixture of gas and hydrocarbon oil under pressure, whereby the volatile constituents of the gas are condensed, the condensed liquid mixing with the oil; the refrigerating liquid is subsequently separated from the mixed hydrocarbons.—J. S. G. T.

Distilling mineral oil; Apparatus for —. E. V. Stone. U.S.P. 1,351,266, 31.8.20. Appl., 14.11.18.

MINERAL oil is distilled in a rotating retort which is slightly inclined to the horizontal. The retort contains a number of iron rods of equal length which break up carbon deposits by their impact due to the rotation of the retort, and the carbon is discharged at the lower end to a conveyor.—W. F. F.

Fuel and process of forming same. D. Markle. E.P. 126,972, 16.5.19. Conv., 11.9.17.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Retorts and the like [for low-temperature distillation]. Merz and McLellan, A. C. Michie, and E. G. Weeks. E.P. 149,733, 14.5.19.

AN apparatus for feeding fuel to low-temperature distillation retorts comprises one or more lateral conduits projecting horizontally into the retort at a level below the normal surface of the fuel. The conduits are open at the top within the retort, and each contains a screw conveyor which causes the fuel to overflow into the retort without the creation of dust and consequent fouling of the condensers which occurs when the fuel is dropped into the retort from a hopper.—W. F. F.

Wood and other carbonaceous material; Process and apparatus for carbonising —. J. F. Wells. E.P. 149,773, 19.5.19.

WOOD, vegetable matter, peat, coal, lignite, and other carbonaceous materials are carbonised in a vertical retort to which air is admitted through the grate to burn the volatile products at the bottom. The hot gases pass upwards through the charge to distil the lighter volatile constituents in the upper part. The carbonised material is withdrawn at the bottom at the moment when the last portion of the volatile product is being consumed and is replaced by the descending fuel.—W. F. F.

Vegetable charcoal; Production of highly active granular —. Verein Chem. Fabr. in Mannheim. G.P. 309,221, 15.4.17.

WOOD in small pieces of appropriate size is impregnated with solutions of electrolytes other than caustic potash, potassium carbonate, and similar compounds of potassium, and carbonised at a dull red heat. It is then lixiviated, impregnated with alkaline solutions (e.g., potassium carbonate), and carbonised at a bright red heat.—J. S. G. T.

Distillation of wood or coal; Process for removing tar from products of —. E. A. Barbet. U.S.P. 1,351,363, 31.8.20. Appl., 6.11.18.

III.—TAR AND TAR PRODUCTS.

Alkali fusions. II. Fusion of sodium benzene-disulphonate with sodium hydroxide for the production of resorcinol. M. Phillips and H. D. Gibbs. J. Ind. Eng. Chem., 1920, 12, 857—860.

THE best yields of resorcinol are obtained by the fusion of 16 mols. of sodium hydroxide with 1 mol. of sodium benzene-*m*-disulphonate for 2 hrs. at 310° C., in the presence of not more than 2—4% of water. (Cf. J.C.S., Nov.)—C. A. M.

Naphthalene and anthraquinone; Nitro-derivatives of —. S. N. Dhar. Chem. Soc. Trans., 1920, 117, 1001—1001.

THE two isomeric tetranitronaphthalenes were obtained by nitrating 1,8-dinitronaphthalene with a mixture of equal volumes of concentrated sulphuric and nitric acids. The hitherto unknown 1,2,6,8-tetranitro compound separates out from this mixture. It does not melt below 300° C. Two trinitro-

β -naphthoic acids melting at 220° C. and 215° C. respectively were obtained by the nitration of β -naphthoic acid. As the result of the nitration of anthraquinone under various conditions four dinitro compounds were obtained, of which two were identified as 1,5-dinitroanthraquinone, and the hitherto unknown 1,3-dinitroanthraquinone, m.p. 210° C., respectively.—G. F. M.

s-Xylidine; Synthesis of —. H. L. Haller, E. Q. Adams, and E. T. Wherry. J. Amer. Chem. Soc., 1920, 42, 1840—1842.

s-XYLIDINE may be prepared from mesitylene by way of mesitylenic acid and its amide, but a more satisfactory process is a modification of that of Willgerodt and Schmierer (Ber., 1905, 38, 1472), starting from *m*-4-xylidine. (Cf. J.C.S., i., 670.) —W. G.

Halogenation. Dhar. See XX.

PATENT.

Reduction of nitro-compounds. E.P. 150,412. See XX.

IV.—COLOURING MATTERS AND DYES.

Cyanine dyes. II. Synthesis of o-amino-cinnamylidene-quinaldine methiodide. W. H. Mills and P. E. Evans. Chem. Soc. Trans., 1920, 117, 1035—1040.

o-NITROCINNAMIC aldehyde was condensed with quinaldine in presence of zinc chloride with the formation of *o*-nitrocinnamylidene-quinaldine, which was reduced to the amino-compound with iron and acetic acid, and the quaternary methiodide of this base was then prepared, the amino-group being temporarily protected by acylation. The compound forms deep reddish-brown solutions, which are turned pale yellow by mineral acids. It dyes wool and silk a rich reddish-brown, but the colour is not fast to light. Its absorption spectrum differs from that of the isocyanines, and the compound shows little analogy in properties to these substances. It has also no appreciable sensitising action on a gelatino-bromide photographic plate.—G. F. M.

Catechin; Constitution of —. I. M. Nierenstein. Chem. Soc. Trans., 1920, 117, 971—979.

THE methylated reduction product obtained from catechin tetramethyl ether by Kostanecki and Lampe (Ber., 1907, 40, 720), and variously regarded as 2,4,6,3',4'-pentamethoxy-3-ethylidiphenylmethane and as 2,4,6,3',4'-pentamethoxy- α -diphenylpropane, is not identical with either of these substances, which have now been synthesised from 2,4,6,3',4'-pentamethoxy-3-ethylbenzophenone and 2,4,6-trimethoxyphenyl-3,4-dimethoxystyryl ketone respectively. The acid, $C_{19}H_{20}O_8$, however, which is obtained by the oxidation of Kostanecki's methylated reduction product, $C_{20}H_{26}O_8$, is shown to be identical with 2,4,6,3',4'-pentamethoxydiphenylacetic acid synthesised from the corresponding diphenylmethyl chloride by the Grignard reaction. It is accordingly deduced that the methylated reduction product is the pentamethoxy- α -diphenylpropane. Catechin itself would therefore be represented by a slight modification of Perkin's chroman formula (Trans. Chem. Soc., 1902, 81, 1172).—G. F. M.

Dyes; Table for the identification of — by means of the spectroscope. J. Moir. J. S. Afr. Assoc. Anal. Chem., 1920, 3, 9—13.

THE table given shows the position of the centre of the absorption-band in the spectra of a large number of dyes as observed in a wave-length spectroscope. The positions range from 425 for Aurantia to 668 for Tetramethylthionine.—W. P. S.

Ultra-filtration. Schmitt. See I.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

[Paper pulp;] *Curtaiment of bleaching powder consumption by the addition of sulphur to the digester liquor [in manufacture of —].* G. K. Spence. Paper, 1920, 26, 19—21.

TABLES of the results of 35 experimental digestions, with and without the use of sulphur, are given. In all cases the sulphur was used at the rate of 1.1% on the weight of stock. It was found that 1.1 lb. of sulphur effected a saving of only 0.92 lb. of bleaching powder (35% avail. Cl). This is a small advantage, since claims that the sulphur leads to increase of yield and strength are not yet proved.—A. J. H.

[Parchment] *paper pulps; Mucilage of —.* F. B. Seibert and J. E. Minor. Pulp and Paper Mag., 1920, 18, 939—942. (Cf. Schwalbe and Becker, J., 1919, 858 A; 1920, 330 A.)

THE presence of hydrocellulose is favourable to the development of mucilage during the beating of paper pulp, and this explains why parchment pulps having a high copper number require less beating than pure cellulose pulps. It is advantageous to subject pulp to a cold acid treatment before beating. This increases the amount of hydrocellulose present, and also the strength of the paper produced.—A. J. H.

PATENTS.

Flexible [fireproof] material for aeroplanes. N. A. T. N. Feary. E.P. 149,745, 15.5.19.

NON-CONDUCTING flexible fabrics are made fireproof and also generally waterproof without loss of tensile strength by coating them with a metal by electrolytic deposition.—A. J. H.

Artificial silk and staple fibres; Treatment of —. A. Lanffs. G.P. 322,141, 3.12.18.

IF suitable organic substances such as sugars, glycerol, and soluble starch be added to the water used for precipitating the fibres, the harmful effects of any lime still present (most of the lime is removed by a preliminary treatment of the water) is much diminished and, especially in dyeing, more even results are obtained.—A. J. H.

Pyroxylin products; Method of making —. J. G. Jarvis. U.S.P. 1,351,652, 31.8.20. Appl., 13.3.19. Renewed 23.6.20.

A FILM is produced by spreading a plastic solution of nitrocellulose and acetylcellulose on a carrier and topping this with a fluid mixture made by the addition of acetone and collodion to a mixture of acetylcellulose, naphthalene, and equal parts of acetone and ethyl acetate. A solution, *e.g.* of chloral hydrate is finally added when the mixture is homogeneous in order to reduce the inflammability of the film.—A. J. H.

[Celluloid] *films; Obtaining products from —.* W. C. Pierson. U.S.P. 1,352,216, 7.9.20. Appl., 27.11.17.

THE celluloid is dissolved in acetone, and thrown out of solution, by the addition of water, as a thick mass which is then washed, dried, and pulverised.—B. V. S.

Paper-stock; Method of reclaiming —. C. Baskerville and C. M. Joyce. U.S.P. 1,351,092, 31.8.20. Appl., 7.10.19.

WASTE inked paper is saturated in a mixture of kerosene, borax, soap, and water.—W. J. W.

Wood-pulp liquor; Method of and means for the de-acidification of raw —. B. Grätz. E.P. 150,571, 26.11.19.

THE liquor is allowed to flow along a trough through which the ashes from lignite or other brown coals are transported in an opposite direction by means of a mechanical conveyor. The cost of neutralisation is small, and the liquor obtained may be used for preparing artificial stone.—A. J. H.

Soda-cellulose waste lyes; Process for treating —. H. Achenbach. G.P. 322,771, 16.2.19.

THE waste liquor passes down a tower, in which it is concentrated from about 5° B. (sp. gr. 1.037) to about 10° B. (sp. gr. 1.075) by means of furnace gases. It can then be evaporated in the usual apparatus without frothing.—L. A. C.

Hemp; Process for manufacturing an elastic imitation —. T. Honda, Assr. to H. Nishimura. U.S.P. 1,351,385, 31.8.20. Appl., 3.7.19.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Printing fabrics with basic dyestuffs. A. Stiegler. Sealed note No. 2035, Bull. Soc. Ind. Mulhouse, 1920, 86, 173—174. Report by C. Sunder. *Ibid.*, 174—175.

THE fixation of basic colours in printing may be advantageously carried out by using lead acetate instead of antimony salts. Cloth is printed with a paste containing 30 g. of basic dye, 100 g. of lactic acid, 500 g. of starch-tragacanth thickening, 180 g. of 50% tannic acid solution, 20 g. of lead acetate, and 170 g. of water; steamed for 1 hr., washed and soaped, and finally chemicked. The lactic acid prevents the formation of the lead colour lake in the printing paste. The colours so obtained are pure, bright, and as fast to washing and light as those obtained with antimony salts. The shades are also heavier. For naphthol-prepared cloth, a steaming for 5 min. is sufficient. Sunder reports favourably on the process but, owing to the sensitiveness of lead salts to hydrogen sulphide, suggests that antimony salts be used in the soap bath.—A. J. H.

PATENTS.

Scouring fibres of vegetable origin; Process for — with the object of accelerating and facilitating subsequent bleaching. E. T. J. Watremez. E.P. 139,457, 25.11.19. Conv., 24.2.19. Addn. to 135,516 (J., 1920, 568 A).

FOR scouring in the cold it is advisable to omit completely the reducing salt from the bath (*loc. cit.*), which may be made by adding in the cold 1 kg. of zinc oxide to a mixture of 40 l. of caustic soda of 30°—35° B. (sp. gr. 1.262—1.320) and 30 l. of Eau de Javelle of 16°—18° B. (sp. gr. 1.125—1.143) and diluting to 1000 l. The fibres are steeped in this solution for 12—24 hrs., rinsed, immediately soured at the boil, rinsed, and then subjected to the bleaching process proper.—A. J. H.

Raw [grege] silk; Process of dyeing —. E. L. Maupai. U.S.P. 1,352,014, 7.9.20. Appl., 14.6.20.

GREGE silk is hardened by immersion in a solution of a metallic salt, washed, and dyed with vat colours.—A. J. H.

Silk fabrics; Machines for finishing —. G. P. Vuono. E.P. 149,842, 27.8.19.

Drying of fabrics [after finishing]. W. Backer. E.P. 150,631, 3.3.20.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Pyrophosphoric acid; Third and fourth dissociation constants of —. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 474—478.

A COLORIMETRIC method is described for the determination of the fourth dissociation constant of pyrophosphoric acid. Thymolphthalein is used as an indicator, and standard solutions of known hydrogen ion concentration consisting of carbonate-bicarbonate mixtures. The value $K_4 = 4.6 \times 10^{-9}$ was found. Other measurements in mixtures of the trisodium and the tetrasodium salts gave $K_4 = 3.6 \times 10^{-9}$. For the third dissociation constant, $K_3 = 7.6 \times 10^{-7}$ was found.—W. S. M.

Alkali chloride solutions; Behaviour of concentrated — during evaporation, in presence of alkali hydroxides. C. Chorower. Z. angew. Chem., 1920, 33, 201—203.

IN connexion with the recovery of potassium salts from vinasses ash by treatment with lime and barium hydroxide, followed by suitable decomposition of the salts, the solubility of alkali chlorides in presence of hydroxides was investigated. An experimental liquor had the following composition:—Cl, 3.559%; OH, 0.9278%; K, 4.792%; Na, 0.933%; S, 0.0591%; SO_4 , 0.0321%; CO_2 , 0.0705%. The liquor was evaporated in a 4-l. vessel, fresh liquor being added at intervals, and the separated salts removed periodically. At various stages, as deposition of salts ceased, the boiling point was taken, after which the specific gravity was determined in a modified pycnometer provided with an asbestos filter, and the sample then analysed. Samples taken after 15, 20, 35, 41, and 48 l. respectively of solution had been evaporated showed boiling points increasing from 110° to 118° , and sp. gr. from 1.295 to 1.370. The chlorine ions diminished from 12.58 to 7.661 g. per 100 g. of solution, and the potassium ions remained almost constant at approximately 17 g. All other ions increased progressively. The figures showed the value Na concentration/OH concentration to be a constant, and the product $Cl \times OH$ also attained a constant value. The author discusses the explanation of the rising Na value and stationary K value by the application of the phase rule.—W. J. W.

Halogens; Solubility of — in the corresponding hydroacids and alkali salts. II. E. Oliveri-Mandalà. Gaz. Chim. Ital., 1920, 50, II., 89—98.

THE solubilities of chlorine in sodium chloride solutions and hydrochloric acid, and of bromine in hydrochloric and hydrobromic acids, have been investigated. (Cf. J.C.S., ii., 614.)—T. H. P.

Carbon dioxide; Determination of — in water-insoluble carbonates. C. S. Robinson. Soil Sci., 1920, 10, 41—47.

DETERMINATIONS were made of the carbonate content of samples of limestone, marl, and soil. The first method used was that of Van Slyke (J., 1919, 40 A), in which the sample was decomposed in a partially evacuated flask containing standard

barium hydroxide. The second method used was a gasometric one, originally proposed for soluble carbonates by Van Slyke (J., 1917, 91D). A special form of finely-graduated cup nitrometer was used, with a tube and special stopper holding the weighed sample introduced between the bottom of the nitrometer and the levelling tube which contained mercury. The apparatus having been rendered air-free, hydrochloric acid is introduced from the cup into the nitrometer and allowed to run down and mix with the sample. After all the gas has been evolved, its volume is read and its weight calculated from tables prepared for the conditions of the method. The gasometric method was found to be the more accurate of the two, but the first method is to be preferred for samples which are low in magnesium carbonate.—J. H. J.

Thiocyanates; Volumetric determination of — with potassium permanganate. R. Meurice. Ann. Chim. Analyt., 1920, 2, 272—273.

THIOCYANATES may be determined by adding to their sulphuric acid solution an excess of standardised permanganate solution and then titrating the excess with hydrogen peroxide solution. The excess of permanganate added should be at least one-half of that required for the actual oxidation of the thiocyanate. Direct titration of thiocyanates with permanganate solution yields low results.—W. P. S.

Sulphuryl chloride; Synthesis of — in presence of organic compounds. G. Cusmano. Gaz. Chim. Ital., 1920, 50, II., 70—80.

IN general, ketones with one carbonyl group increase the velocity of combination of chlorine with sulphur dioxide to form sulphuryl chloride, this property disappearing when a halogen, nitro- or sulphy-group is introduced into the molecule at any distance from the carbonyl group; the presence of carboxyl is without effect. In $\alpha\alpha$ -diketones, one of the carbonyl groups may influence the other in the same way as a negative group does. The lack of accelerating action exhibited by the quinones and certain other compounds is ascribed to the formation of stable compounds with either the chlorine or the sulphur dioxide.—T. H. P.

Barium peroxide; Reactions of — with other oxides. Investigations on some rapid low temperature reactions by means of heating curves. J. A. Hedvall and N. von Zweigbergk. Z. anorg. Chem., 1919, 168, 119—136.

THE reactions between barium dioxide and a large number of other oxides were studied by means of heating curves, as described in a previous paper (this J., 1919, 11 A). Of the oxides examined only SnO , SnO_2 , and ZrO_2 had no action at all. Purely catalytic decomposition of the barium dioxide was brought about by MgO , CaO , CuO , CdO , La_2O_3 , and CeO_2 . In other cases the decomposition of the dioxide was followed by combination with the barium oxide formed, e.g., with ZnO , Al_2O_3 , and TiO_2 . Cu_2O and Bi_2O_3 were oxidised by the barium dioxide, and with the following oxides oxidation occurred followed by combination with the reduced barium oxide:— As_2O_3 , Sb_2O_3 , Sb_2O_5 , Cr_2O_3 , U_3O_8 , MnO , Mn_2O_3 , Mn_2O_5 , MnO_2 , Fe_2O_3 , NiO , and CoO . In some cases the reaction took place with great violence, notably with Cu_2O , V_2O_5 , Sb_2O_3 , Cr_2O_3 , MoO_3 , and MnO . (Cf. J.C.S., 1920, ii., 35.)—E. H. R.

Hydrogen peroxide; Electrolytic production of —. F. W. Skirrow and E. R. Stein. Trans. Amer. Electrochem. Soc., 1920, 69—79. [Advance copy.]

RESULTS obtained by the electrolytic decomposition of sulphuric acid, and of sodium and potassium bisulphate solutions, showed that the current efficiencies with which persulphuric acid was formed

were about the same in all three solutions. Platinum, with the possible exception of manganese dioxide, alone affords a suitable anode material. Sodium persulphate solutions can be produced of a much higher concentration than can persulphuric acid, without loss of current efficiency. Distillation of potassium persulphate with sulphuric acid and water gave reasonably high yields—about 80%—of hydrogen peroxide. In the case of sodium persulphate, in no case did distillation yield more than 9% of the theoretical amount of hydrogen peroxide. Distillation of persulphuric acid or sodium persulphate solutions would need to be preceded by extremely careful removal of all catalytic impurities.

—J. S. G. T.

Liquid air; Rectification of —. E. Barbet. *Chim. et Ind.*, 1920, 4, 147—150.

In liquid air rectifiers in which no means are provided for drawing off argon, it is impossible to attain absolute purity of the nitrogen or oxygen. It is fallacious to assume that nitrogen, showing 0.1–0.2% O₂ on analysis, is of 99.9–99.8% purity, as this content of oxygen implies an even higher proportion of argon, the latter being more volatile and not so readily arrested by the reflux condensers. Removal of argon from the rectifying column may be effected with even more facility than the separation of amyl alcohol from ethyl alcohol, and the employment of regulators and thermometers for this purpose is essential. Argon of any selected concentration may be drawn off continuously at certain plates of the column, preferably the lower ones, without tedious manipulation of the rectification process or multiplication of control tests.

Mixtures of gases. Weaver and Palmer. *See* XXIII.

PATENTS.

Sulphuric acid; Utilisation of the waste gases evolved in the concentration of —. H. Petersen. G.P. 302,534, 23.2.17.

THE waste gases are cooled by using them to effect a preliminary concentration of cold sulphuric acid, and are then passed into the lead chambers, in place of the water or steam commonly employed.

—J. S. G. T.

Furnace for carrying out endothermic gas reactions [e.g., production of nitric oxide]. Elektrochem. Werke, G.m.b.H. E.P. 116,503, 5.6.18. Conv., 23.3.17. Addn. to 5281 of 1911 (J., 1911, 812).

In an electric arc furnace constructed in accordance with the former patent, a double-walled, water-cooled metallic tube passes through the upper cover of the furnace. The gases from the furnace pass directly from the arc zone into this tube, which is of such dimensions that the gases leave it at about 1200°–1500° C. The concentration of nitric oxide is thereby increased to 2.5%, compared with 1.5% hitherto attained.—J. S. G. T.

Nitric oxide; Production of — in gas engines. F. Gerhardt. G.P. 321,981, 9.12.15. Addn. to 303,255 (J., 1919, 891 A).

THE exhaust gases of the engine are utilised to pre-heat the air or gas stream employed to produce turbulence of the charge.—J. S. G. T.

Gaseous reactions; Catalytic process for effecting — more especially for the production of oxides of nitrogen from mixtures of ammonia and air or oxygen. Permutit A.-G. G.P. 298,981, 2.5.15.

THE gaseous mixture is passed over material of the

nature of aluminate-silicates, in which the aluminium has been displaced by one or more elements, the oxides of which are soluble in alkali; in addition, or alternatively, the alkali of the aluminate-silicate may be entirely replaced by one or more heavy metals. Natural base-exchanging silicate minerals or artificially produced aluminosilicates of heavy metals, such as chromium, manganese, cobalt, nickel, etc., may be employed. A product containing cobalt and tungsten when employed as catalyst affords practically a quantitative yield of chlorine by the oxidation of hydrochloric acid; and a product containing nickel and boron may be used for the oxidation of a mixture of sulphur dioxide and air to sulphur trioxide.

—J. S. G. T.

Ammonia; Synthetic production of —. H. C. Greenwood. U.S.P. 1,312,534, 12.8.19. Appl., 15.2.18.

HYDROGEN and nitrogen are passed over a heated catalyst at a velocity of a million litres or more per hour for each litre of catalyst space. Using 1½ million litres of the mixture at 100 atm., yields of about 15 kg. of ammonia per hr. per litre of catalyst space may be obtained. It is advisable to use 10–20% excess of nitrogen.—W. J. W.

(A) *Ammonia; Production of* —. (B) *Ammonia synthesis and catalyst therefor*. (C) *Ammonia synthesis*. (D, E, F) *Production of ammonia*. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. (A) 1,352,174, (B) 1,352,178, (C) 1,352,179, (D) 1,352,180, (E) 1,352,181, and (F) 1,352,182, 7.9.20. Appl., (A) 23.3.16, (B) 17.3.19, (C) 8.9.19, (D, E, F) 14.1.20.

A GASEOUS mixture containing nitrogen and hydrogen is brought under high pressure into contact with a catalyst comprising (A) an alkali metal cyanamide; (B) a metal capable of forming a nitride at an ammonia-forming temperature, together with a compound of an alkali metal and carbon or an alkali metal intimately associated with carbon, manganese, and iron; (C) a compound containing an atom of carbon united to two nitrogen atoms (at a temperature below 550°); (D) a cyanamide composition including cobalt; (E) a cyanamide composition containing manganese, or (F) a cyanogen compound containing potassium.—C. I.

Cyanogen compound of an alkali metal; Process of obtaining the —. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,352,175, 7.9.20. Appl., 13.7.17.

AN alkaline-earth carbonate mixed with a cyanide is acted upon by free nitrogen yielding an alkaline-earth cyanide. This is converted into an alkali cyanide by interaction with an alkali carbonate.

—C. I.

Metallic cyanides; Process and means for producing —. C. P. Hidden, Assr. to Nitrogen Products Co. U.S.P. 1,352,192, 7.9.20. Appl., 18.11.18.

A MIXTURE of carbon, alkali carbonate, and catalytic material is caused to travel down a furnace-heated retort in presence of an ascending current of nitrogen. The heating is regulated so that no appreciable formation of cyanide takes place until the charge has reached the lower portion of the retort, at which stage the temperature is suddenly raised, the cyanide produced being rapidly cooled as it emerges to prevent loss from volatilisation.

—W. J. W.

Nitrogen; Process for fixing atmospheric —. C. P. Hidden, Assr. to Nitrogen Products Co. U.S.P. 1,352,193, 7.9.20. Appl., 5.7.19.

FOR the fixation of nitrogen by means of a porous charge, constituents of which are capable of combining with free nitrogen to form a cyanide and

carbon monoxide, the charge is first heated to a cyanide-forming temperature by direct gaseous convection, the gas employed being such as to prevent formation of cyanide. Nitrogen, preheated to the reaction temperature, is then introduced, after which cool nitrogen is passed in to remove the carbon monoxide formed, and at the same time to cool the product below the temperature at which carbon monoxide reacts on the cyanide.—W. J. W.

Potassium sulphate; Manufacture of —. Fabr. de Prod. Chim. de Thann et de Mulhouse. E.P. 137,519, 30.12.19. Conv., 30.12.18.

POTASSIUM sulphate is prepared by the action on finely-powdered potassium chloride of sulphuric acid of such strength (70–72% H_2SO_4) as to render the moist mixture as pulverulent as possible. The mixture is heated in three stages, first at 100°–120° C., with stirring, then at 300° C., and finally at 800° C. By using a slight excess of sulphuric acid a sulphate is obtained almost or quite free from chloride, especially if iron is replaced by brick in the furnaces used for the last two stages. Potassium bisulphate may be substituted for sulphuric acid.—C. I.

Rock salt brine or solutions of rock salt in water; Removal of calcium and magnesium from —. F. A. Freeth and L. A. Munro. E.P. 119,707, 15.2.19.

THE usual process for the purification of brine (L. Mond, E.P. 4175 of 1874 and 3599 of 1878) is modified by adding the sodium carbonate and calcium hydroxide with gentle stirring, the reagents being maintained at 25° C. The precipitate thus formed settles readily.—C. I.

Hypochlorites; Electrolytic apparatus for the direct production of —. P. Pestalozza. E.P. 150,214, 19.2.19.

A VAT is subdivided into a number of cells by transverse partitions, the lower portions of which are constructed of the same material as the vat, the remainder being constituted of electrically conducting material serving as anode for one cell and cathode for the adjacent cell. The several cells communicate with one another by apertures in the partitions, these being staggered. A double series of cooling pipes, constituted preferably of glass, and built up of sections connected together by elastic couplings, is immersed in the cells, the one series traversing the even-numbered cells and the other the odd-numbered cells.—J. S. G. T.

Alumina; Process for the manufacture of —. J. Morel. E.P. 149,769, 17.5.19.

ALUMINIUM sulphate is obtained by treating bauxite with a mixture of sulphur dioxide, air, and steam at a temperature not above 800° C. in a Hargreaves or other suitable furnace. The mass is treated with hot water, the solution filtered, concentrated, heated to boiling point in a closed exhaust apparatus, and a solution of sodium thiosulphate added, $\text{Al}_2(\text{SO}_4)_3 + 3\text{Na}_2\text{S}_2\text{O}_3 = \text{Al}_2\text{O}_3 + 3\text{SO}_2 + 3\text{S} + 3\text{Na}_2\text{SO}_4$. The iron remains as ferrous sulphate in solution. The mixture of alumina and sulphur is washed, dried, and calcined. Part of the sulphur dioxide produced is utilised in the first stage of the process and part in regenerating sodium thiosulphate from sodium sulphide produced by reduction of sodium sulphate by carbon. The first stage of the process can be accelerated by passing the gas mixture over an oxide of iron catalyst or adding to the bauxite 1–2% of aluminium or other chloride.—C. I.

Aluminium nitrate; Preparation of —. J. J. Hood. E.P. 149,783, 20.5.19.

NORMAL aluminium nitrate is prepared by double

decomposition of aluminium sulphate with calcium, barium, ammonium, or potassium nitrate.—C. I.

Lead arsenate; Method of making —. E. O. Barstow, Assr. to The Dow Chemical Co. U.S.P. 1,349,707, 17.8.20. Appl., 28.8.18.

LEAD oxide, in excess, is mixed with lead acetate and the resulting basic lead acetate is separated. A solution of the basic acetate is continuously mixed with arsenic acid, lead arsenate being precipitated.—A. G.

Soda, etc.; Process of depositing —. W. F. Watterson. U.S.P. 1,350,128, 17.8.20. Appl., 8.9.19.

THE crystals are formed around a thin stick of relatively small mass compared with the mass of the crystals which grow upon it. The whole, including the stick, is finally broken up.—W. H. C.

Zirconium oxide; Method of obtaining —. L. E. Barton, Assr. to The Titanium Alloy Manufacturing Co. U.S.P. 1,351,091, 31.8.20. Appl., 24.9.19.

MATERIAL containing zirconium oxide is melted with a carbonaceous reducing agent, the zirconium cyanonitride produced being then caused to react with an alkali sulphate.—W. J. W.

Thorium; Recovery of —. L. W. Ryan, Assr. to Lindsay Light Co. U.S.P. 1,351,439, 31.8.20. Appl., 29.5.18.

THORIUM is precipitated as a metaphosphate from a dissolved thorium salt.—C. I.

Alkali-metal hydroxides; Process of producing —. S. S. Sadtler. U.S.P. 1,351,693, 31.8.20. Appl., 21.3.19.

SODIUM hydroxide is produced by interaction of disodium phosphate (284 pts.) and calcium hydroxide (148–222 pts.).—C. I.

Hydrogen sulphide; Process of manufacturing —. K. Ikeda. U.S.P. 1,351,755, 7.9.20. Appl., 12.11.17.

SULPHUR and fuel gas are caused to interact in the presence of a catalyst.—C. I.

Oxide or oxides of manganese; Method of producing —. B. F. Lovelace. U.S.P. 1,352,208, 7.9.20. Appl., 24.4.19.

A SOLUTION of ammonium carbonate is electrolysed in a single compartment cell at a temperature below 35° C., one of the anodes containing manganese.—B. V. S.

Sodium bicarbonate and hydrogen; Method of producing —. A. Nagelvoort, Assr. to The Nitrogen Corp. U.S.P. 1,352,211, 7.9.20. Appl., 7.2.20.

IN the ammonia-soda process the ammoniated brine is treated with carbon dioxide diluted with hydrogen. The presence of the hydrogen keeps down the temperature and thus favours the formation of large crystals of sodium bicarbonate. The separated hydrogen is collected for use in the synthetic preparation of ammonia.—B. V. S.

Hydrogen peroxide; Process for stabilising solutions of —. A. Queisser. G.P. 321,616, 20.4.19.

WATER-SOLUBLE complex salts of salicylic acid with borax or disodium phosphate are added to solutions of hydrogen peroxide.—L. A. C.

Carbon and the like; Production of substantially pure —. R. Williams, Assr. to Nitrogen Products Co. U.S.P. 1,352,162, 7.9.20. Appl., 24.1.18.

CARBON monoxide is converted into carbon dioxide and free carbon by heating at a temperature below

700° C. in the presence of a catalyst, the latter being agitated to facilitate the conversion.

—D. F. T.

VIII.—GLASS; CERAMICS.

Refractories; Physical characteristics of specialised —. (Part 3) *Electrical resistivity at high temperatures*. M. L. Hartmann, A. P. Sullivan, and D. E. Allen. Trans. Amer. Electrochem. Soc., 1920, 1—15. [Advance copy.] (See also J., 1920, 365 A.)

THE electrical resistivity of nine commercial refractories was determined. Fireclay bricks of grade A quality and coarse texture, bauxite bricks, and silica bricks with a lime-bond gave regular resistivity curves. Carborundum bricks containing 95% of "carbofrax C" and 5% of bond gave similar curves, the resistivity being constant when the bricks were maintained at 1500° C. "Carbofrax B," on the contrary, showed a rapid decrease of resistivity with increasing time of heating. Recrystallised carborundum ("Refrax") gave quite regular curves, the resistivity being low at all temperatures. With magnesia bricks there was a marked difference between the resistivity curves during heating and cooling and a peculiar flattening of the heating curves (indicating a constancy of resistance) between 1000° and 1150° C., which appears to indicate a physical change in the structure of the magnesia. The cooling curves did not show this flattening. The difference between the resistivity curves during heating and cooling of bricks of natural zirconia is very marked. On heating, the resistivity fell very rapidly until a temperature of 1200° C. was reached, after which it fell very slowly, indicating that a permanent change occurs on heating zirconia to 1200° C. Coarse-grained chrome bricks possessed low resistivities at all temperatures, the resistivity remaining practically constant between 1100° and 1200° C., increasing between 1200° and 1350° C., and again decreasing from 1350° to 1500° C. The cooling curves differ greatly from the heating curves. A table showing the resistivities of the materials examined when cold and at various temperatures between 800° and 1500° C. is given.

Porcelain [fired at] Seger cone 7—9. T. Hertwig. Sprechaal, 1920, 53, 363—365.

PORCELAINS maturing at cone 7—9 should be used extensively in the future on account of the saving in fuel as compared with those fired at cone 13—14, but to obtain the best results the ovens must be re-designed and additional fires employed. All German hard porcelains may be biscuit-fired at cone 9 when very finely ground. In soft French porcelains the clay:quartz ratio is less important than in the harder German product. Porcelains fired at cone 7—9 have a slight bluish tinge if quartz is used, but this disappears if flint is substituted. A number of formulæ for bodies and for glazes of various colours are given. The materials used for a body for glazed porcelain should not be ground for more than 24 hrs., as if it is too finely ground the glaze subsequently applied will craze.

Materials for bodies which are not to be glazed may be ground for 70—100 hrs.—A. B. S.

IX.—BUILDING MATERIALS.

Portland cement, hydraulic lime, and volcanic ashes; Long-time tests of —. I. Hiroi. J. Coll. Eng., Tokyo Imp. Univ., 1920, 10, 155—172.

PARTICULARS are given of an investigation commenced over 20 years ago in connection with the manufacture of concrete blocks for harbour works. No case of decomposition of cement by the chemical action of sea-water alone has been observed, except where defective cement was used. It is concluded that Portland cement of good quality, properly gauged, can be made to resist the action of sea-water for an unlimited time. "Neat" cement briquettes attained their maximum strength in less than a year and then rapidly became weaker, in some cases losing their tensile strength entirely in four or five years, though still remaining intact and even showing increased compressive strength. The tensile strength in air and in fresh water increased similarly at first, but after the initial rise the changes were irregular, although showing a tendency to gradual increase. "Neat" hydraulic lime gave similar results in air and in fresh water, but attained a maximum strength in salt water after three years, after which a decrease occurred, with total disintegration in 6—7 years. Prolonged tests of mortar made with 1 part of cement to 2 of sand showed progressive increases in strength with age, no sign of disintegration being observed; the ultimate tensile strengths attained were about 85 and 50 kg. per sq. cm. in air and in sea-water respectively. Similar tests with hydraulic lime mortar indicated an ultimate maximum tensile strength of about 20 kg. per sq. cm. With 1:3 cement-sand mortar the mean final strengths after 22 years in air, fresh water, and sea water respectively were as follows: Tensile, 70, 42, 37; crushing, 620, 500, 350 kg. per sq. cm.; 1:3 hydraulic lime mortars gave similar results. Tests of the crushing strength of mortar briquettes made with coarse beach sand, "standard" sand, and sand which passed through a sieve with 220 meshes per sq. cm. confirmed the superiority of the coarser sands, which gave results 50% or more higher than the fine sand. The strength of mortars in sea

water appears to be nearly in inverse ratio to the proportion of sand present; the most regular increases in strength were shown with 1:2 mortar. The use of volcanic ashes in mortar is of no advantage in air, but in sea water considerably increased strength results from using properly proportioned mixtures of suitable ash with cement and sand. Comparative tests of briquettes prepared by ramming the mortar mixtures into moulds and by pouring indicated that the early superiority of rammed mortar is maintained throughout during use. The proportion of water used appears to have no ultimate effect on the strength of mortar.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Blast furnaces; Variations in the heat supplied to — and their effect on the fuel consumption. W. W. Hollings. Iron and Steel Inst., Sept., 1920. [Advance proof.] 12 pages.

WHEN an addition is made to the supply of heat to a blast furnace the economy in fuel exceeds the theoretical equivalent of the heat added. It is shown that any variation in the heat supplied involves a secondary series of changes in the heat developed and absorbed within the furnace, and the ultimate calorific effect is the sum of an infinite geometric series of which the primary variation is the first term. The theory is the outcome of an attempt to explain the unsatisfactory results obtained at the Brymbo steel works with a dry air blast, and it is shown that for countries with such a low average moisture as England it does not pay to instal the dry-blast. Crushing of the charge to a uniform size may be expected to result in a considerable saving of fuel. The process of blowing with air slightly enriched with oxygen is not likely to result in an appreciable economy.

—T. H. Bu.

Electric furnace; Consumption of energy by the — in the manufacture of pig iron etc. A. Coutagne. Rev. Mét., 1920, 17, 450—468.

A LARGE amount of experimental data obtained in various operations using a four-phase electric furnace of 800—1000 kw. capacity is given. The energy required for the reduction and fusion of iron in the manufacture of pig iron from ore containing 45—55% Fe and from turnings and scrap containing 90% Fe, for the reduction and fusion of manganese in the manufacture of 75% ferromanganese, and for the reduction and fusion of silicon in the manufacture of ferrosilicon of various grades from iron scrap and turnings is fully considered. In the silicon experiments the questions of capacity of furnace and the richness of the alloys produced are dealt with, as is also the loss of silicon as silica by volatilisation. The consumption of energy required in the manufacture of the ternary alloys of iron, silicon, and manganese from ore and scrap iron is also given. Comparison of the experimental data with theoretical data shows that the useful electric

thermic effect for an electric furnace of 800—1000 kw. capacity is near 60% and for a furnace of 1000 kw. capacity about 70%. Comparative thermal balance sheets show that the electric furnace working with and without gas compares favourably with a blast furnace working under similar conditions.—J. W. D.

Steels; Electric — C. G. Carlisle. Iron and Steel Inst., Sept., 1920. [Advance proof.] 23 pages.

ANALYSES of electric furnace slags and the accompanying metal confirm the contention that the slag must be free from metal oxides before sulphur in any considerable degree can be transferred from metal to slag. The elimination of sulphur is greater the smaller the furnace. Phosphorus cannot be reduced in like degree. Production of sound metal depends upon the control of slags especially during the refining period. Results of tests on electric steels made to Air Board specifications are given. On an equal number of test-pieces a greater percentage of success was obtained than with Siemens steels of the same composition. Compression tests in which the load was applied quickly in order to find out if the steel would resist shock without breakdown showed up clearly the value of the electric steels, and workshop practice over a long period bore out the compression test results. Electric steels gave higher crushing loads and yield points than crucible steels. Particulars of practical tests with electric steel dies and other tools are given. A high-speed drill of electric steel gave record results. Tests on an aeroplane exhaust valve of electric steel showed a marked increase in strength at temperatures over 800° C. In the author's opinion a 15—20-ton electric furnace would, under steady conditions, produce as cheaply as a 50-ton acid Siemens furnace.—T. H. Bu.

Steel; Decaridation of — with hydrogen. J. H. Whiteley. Iron and Steel Inst., Sept., 1920. [Advance copy.] 14 pages.

HEATING a section of a steel plate in hydrogen at temperatures below 950° C. failed to remove the banded structure or micro-ghost lines (J., 1920, 452 A). Samples of Armeo iron containing numerous visible particles identified as iron oxide (FeO) and iron oxide-sulphide eutectic were subjected to the action of hydrogen at various temperatures, the experiments being made with small sections and also with strips 1/400 in. thick. Oxide was removed very slowly below 950° C., but the rate increased with the temperature. At 1300° C. the thin strips appeared to be decaridised in 1 hr. With thin turning the speed of decaridation was greater, probably due to the numerous cracks. It was found that one steel was decarburised and another carburised under the same conditions in hydrogen. To determine correctly oxygen as oxide in steel a temperature of 1000°—1200° C. is necessary. The drillings or turnings should be as fine as possible, and the possibility of the evolution of carbon monoxide and dioxide must be borne in mind.—T. H. Bu.

Cast steel; Studies of the macrostructure of — F. G. Allison and M. M. Rock. Chem. and Met. Eng., 1920, 23, 383—389.

THE influence of the temperature at the time of pouring and the conditions of cooling etc. as revealed by the inspection of photographs of polished and etched surfaces and the conditions of dendritic growth are discussed. A number of photographs are included in the paper.—W. H. C.

Carbon steels heated in vacuo; Surface changes of — E. H. Hemingway and G. R. Ensminger. Amer. Inst. Min. Eng., Aug., 1920. Chem. and Met. Eng., 1920, 23, 366.

AFTER heating a steel containing 1.01% C in *vacuo*.

for 6 hrs., at 1000° C., there appeared on the surface, when examined at 500 magnifications, delicate pearlitic grains representing a structure stable below the critical point. Independent of this structure was a second system consisting of deeply marked polygonal crystals representing γ -iron boundaries, and also a third system independent of either, which was thought to represent the boundaries of former γ -crystals which had been absorbed by crystalline growth. This outside layer of carbon-free iron was very thin, although with steels of lower carbon content a layer of greater depth was obtained. A study of the deposits found inside the vacuum tube suggested that this outside layer consisted of ferrite volatilised at the high temperature and redeposited below the temperature at which solid solution exists. Any iron oxide existing on or in the steel would tend to cause decarburisation by breaking down the cementite.

—J. W. D.

Steel; Nitrogen in — and the erosion of guns.

H. E. Wheeler. Amer. Inst. Min. Eng., Aug., 1920. Chem. and Met. Eng., 1920, 23, 366.

SMALL steel cylinders of various compositions were heated in ammonia for 20 hrs. at 650° C. and then cooled in the same atmosphere. Nascent nitrogen from such treatment forms Fe_3N , which is stable below 450° C., and penetrates the steel. Carburisation also occurs in low-carbon steel by pyridine or hydrocarbon impurities in the gas, while decarburisation takes place in hypereutectoid steels. In alloy steels the alloying elements do not combine with the nitrogen, but affect the penetration only as they affect the carbide. White cast-iron becomes coated with a layer of solid Fe_3N containing 1% C. Cold work greatly assists the penetration, the work apparently shattering the cementite so that it is more easily dissolved and retained in solid solution by the combined action of heat and nitrogen. These results were so similar to the phenomena accompanying gun erosion that it is suggested that the hard white layer on the inside of an eroded gun is a locally cold-worked austenitic case due to the penetration of nitrogen at the high pressure and temperature produced during explosion.—J. W. D.

Flakes [in nickel steel]; Cure of — by proper heat treatment. C. S. Crouse. Chem. and Met. Eng., 1920, 23, 329–332.

FLAKES and streaks in nickel steel forgings due to cooling strains were practically eliminated by casting in octagonal instead of in square moulds, stripping the ingots, and cooling slowly and uniformly in ashes instead of quickly in air. Flakes due to strains set up in the forgings during heat treatment were reduced considerably by adopting the following modified procedure. All forgings were preheated to 500°–700° F. (260°–370° C.) before charging. Large forgings were then raised to 1475° F. (800° C.) in 8–12 hrs., held at that temperature for 1½ hrs., and then quenched in water for 1½ min. On withdrawing from the water they were charged into a tempering furnace heated to 900°–1050° F. (480°–570° C.), raised to that temperature in 2–4 hrs., maintained uniform for 3 hrs., then withdrawn to a closed pit and cooled to below 600° F. (315° C.), with the pit covers closed. Small forgings were subjected to a similar treatment except that they were quenched in water for 1 min. only from a temperature of 1500° F. (820° C.) after being kept for 2 hrs. at this temperature. By the above heat treatment failures were reduced to 15% of the total.—J. W. D.

Nickel-chromium steels; Temper-brittleness of —.

R. H. Greaves and J. J. A. Jones. Iron and Steel Inst., Sept., 1920. [Advance proof.] 48 pages.

On reheating tough and brittle specimens of various

nickel-chrome steels in pairs to temperatures within the embrittling range, identical Izod impact figures were reached in a period of time which increased the lower the reheating temperature. The embrittling range was lower for electric than for open-hearth steels. Tempering within or below the embrittling range introduced two opposing tendencies—a softening effect tending to increase the impact figure and an embrittling effect tending to decrease it. Short periods of tempering (less than 30 mins.) did not induce brittleness. The order of susceptibility of various steels to develop temper brittleness is: acid open-hearth steel, electric steel, crucible steel. Of nickel chromium steels the softer steels are the least susceptible. As the temperature of hardening is raised the impact figure of the tempered steels becomes distinctly lower. Vanadium had no effect on susceptibility, and chromium steels showed the same order of brittleness as nickel-chromium steels. Molybdenum steels showed very slight susceptibility. Nickel steels showed various degrees of susceptibility, and carbon steels with less than 0.045% S and P showed no tendency to develop brittleness. Even in the unhardened state nickel-chromium steels showed a tendency to brittleness. Heating in carbon dioxide caused a decided reduction of susceptibility. Heating and cooling curves showed no certain indication of a critical point in the embrittling range. The density of steel after water cooling is a trifle less than after slow cooling. The electrical resistivity of tough and of brittle material is identical. There is no apparent difference in the hardness of the two varieties. The elastic limit of the water-cooled specimens is generally lower than that of the slowly cooled steel.—T. H. Bu.

Uranium steels. E. Polushkin. Rev. Mét., 1920, 17, 421–437.

A SERIES of experiments carried out on steels containing increasing quantities of uranium up to 7% show that the Acl point is not affected, while the Ar1 point is not affected up to 2% U, but is slightly lower with increased quantities. Uranium is present in the steels either as oxide or carbide. Under the microscope the oxide has a dark-grey colour with a slightly bluish tint, and the carbide on heat tinting acquires characteristic blue, green, and violet colours, which become bluish-grey if the heating is prolonged. The carbide is hard, well-crystallised, contains small white crystals, and does not enter into solid solution with iron even at 1250° C. It has a tendency to produce a pearlitic structure which becomes dark with badly formed lamellae as the quantity of uranium increases. The formula of the carbide is probably UC. Mechanical tests indicate that with low carbon content uranium raises the elastic limit and the ultimate stress, while the ductility remains unaffected or is slightly increased. When the carbon exceeds 0.6%, however, the increase in the elastic limit and ultimate stress is accompanied by a lowering of the ductility. Uranium increases the hardness but does not influence the impact or alternating tests. The properties of alloy steels were apparently not greatly improved by the addition of uranium, although nickel-uranium steels appeared to have a ductility superior to that of ordinary nickel or nickel-chromium steels.—J. W. D.

Galvanised iron; Deterioration of — by smoke.

Wislicenus. Z. angew. Chem., 1920, 33, 204.

Tests by Siedler (Rauch und Staub, 1920, 10, 43) show that galvanised iron is unsuitable for roofing in districts where it is exposed to smoke and gases from factories, railways, and house chimneys. Sulphur dioxide, in presence of moisture and oxygen, attacks it rapidly; on the other hand, dry sulphur dioxide has only a slight effect. A mixture of sulphur dioxide and carbon dioxide is very cor-

rosive; moist carbon dioxide alone is less so. Microscopical examination of corroded galvanised iron shows the presence of minute cavities and of sulphate containing ferric oxide, the formation of which is due to galvanic action or to actual solution of the zinc coating. Soot may be a contributory factor to corrosion by acting as a catalyst, and deterioration may also be brought about by the action of sulphuric acid formed by oxidation of the sulphurous acid in the gases.—W. J. W.

Zinc; Extraction of — in the open-hearth furnace with simultaneous recovery of zinc oxide. R. W. Müller. *Stahl u. Eisen*, 1920, 40, 1193—1196.

A CHARGE made up of 2000 kg. of pig iron, 3000 kg. of scrap and bars, and 8000 kg. of galvanised iron scrap, together with 100—150 kg. of coke, was melted in a 12—15-ton open-hearth furnace. The zinc was volatilised and oxidised and passed out with the outgoing hot gases as zinc oxide vapour. The gases leaving the furnace at 1500° C. were drawn by means of an exhaustor through a tubular cooling arrangement and were cooled to 150° C. From the exhaustor the gases passed through a settling chamber which served the double purpose of cooling the gases still further, and of reducing their velocity before passing to the filtering apparatus. A large proportion of the zinc oxide was deposited on the floor of this chamber, the remainder being recovered in the filtering chamber, which consisted of a large number of iron pipes containing bags of fine texture. The zinc oxide recovered had the composition 96.61% ZnO, 2.07% PbO, 1.28% Fe₂O₃, 0.04% MnO, 0.19% SO₂. —J. W. D.

Tin plating from alkaline tin baths by the use of addition agents. F. C. Mathers and W. H. Bell. *Trans. Amer. Electrochem. Soc.*, 1920, 41—44. [Advance copy.]

COPAIBA balsam, rosin, and to a lesser extent similar organic fatty acids or acid-containing substances were found to be satisfactory addition agents in producing smooth, adherent electrolytic deposits of tin from sodium stannite baths. The baths gradually deteriorated so that finally satisfactory deposits could not be obtained.—J. S. G. T.

Lead plating from sodium hydroxide lead baths by the use of addition agents. F. C. Mathers. *Trans. Amer. Electrochem. Soc.*, 1920, 35—39. [Advance copy.]

GUM sandarac, gum albanum, resin, and oleic acid were found to be satisfactory addition agents for diminishing the formation of loosely adhering crystals on the lead deposits from electrolytic baths of lead acetate dissolved in excess of sodium hydroxide solution. Other gums, resins, and fatty acids were also satisfactory. A suitable concentration of bath is: 7.3% of crystallised lead acetate, 20% of sodium hydroxide, 0.3—1% of addition agent. As high a temperature as possible should be employed. The anode current density should not exceed 1 amp. per sq. dm. A cathode current density of 1.5—2 amps. per sq. dm. may be employed. The deposits are less resistant to sulphuric acid than those afforded by acid lead baths. —J. S. G. T.

Antimony; Determination of — in lead-antimony alloys. L. Bertiaux. *Ann. Chim. Analyt.*, 1920, 2, 273—278.

FIVE g. of the sample (e.g., antifriction metal) is dissolved by heating with 40 c.c. of concentrated sulphuric acid and 10 g. of potassium sulphate, the solution cooled, diluted with 200 c.c. of water, 50 c.c. of hydrochloric acid and 2 drops of a 0.1% solution of Poirrier's Orange are added, and the

mixture is titrated with standardised permanganate solution. As soon as all the antimony has been oxidised the next drop of permanganate solution added reacts with the hydrochloric acid yielding free chlorine which at once bleaches the colouring matter. Lead, bismuth, tin, copper, and arsenic do not interfere; iron is titrated together with the antimony. The iron may be determined colorimetrically with thiocyanate in the titrated solution and an allowance made for its quantity.—W. P. S.

Solid state of aggregation; Theory of the —. A. Van der Werth. *Z. physik. Chem.*, 1920, 95, 129—138.

SPECIFIC heat and mechanical solidity both depend on molecular attraction and furnish a measure of the resistance with which a substance opposes any force which tends to disrupt it. It is possible to draw quantitative conclusions in connexion with the mechanical properties of solid substances, e.g., metals, from simple thermal data. (*Cf. J.C.S.*, ii., 583.)—J. F. S.

After-corrosion of firearms. Huff. See XXII.

Steel. Dovey. See XXIII.

PATENTS.

Electrical furnaces [for melting and refining steel].

F.I.A.T. Fabbr. Ital. Automobili Torino. E.P.

(a) 121,485, 12.12.18, and (u) 134,810, 10.3.19.

Conv., 12.12.17 and 2.11.18.

(A) The electrodes employed in an electric furnace for melting and refining steel etc. are protected from the point where they receive current to their entrance into the furnace, against the action of the outside air, by a telescopic tube the movable member of which is secured to a terminal clamp, and slides airtight against a fireproof ring secured to the fixed member, which is provided with a double wall for water circulation. Fireproof insulating rings are provided inside the fixed member. Means are provided for tilting the furnace for purposes of pouring etc., and for removing the electrode holders together with the roof of the furnace. The furnace hearth is made conducting by the addition of suitable substances to the refractory employed. (B) The electrodes are secured to their supports by means of an angle bar. The cooling cylinders rest upon the furnace roof and slide within guide rings provided at the lower ends of the uprights of the electrode holders.—J. S. G. T.

Electric furnaces. D. de Luca. E.P. 150,532, 2.9.19.

AN electric furnace adapted for the production of cast iron from scrap etc. comprises a metal frame covered with sheet metal and five arches of refractory brickwork, four of which are arranged to form the side walls of the furnace and rest on the fifth, which forms the base. The corners and sides of the furnace are reinforced by angle irons. The arches are lined with flat brickwork, and the intermediate space is filled with a protective refractory material, the brickwork lining being also covered with a protective coating. A filling of binding material is arranged between the arches and the metal sheet enclosing the entire brickwork. A tapping hole is arranged on one side of the furnace. The movable cover is provided with openings and devices for mounting the electrodes. —J. S. G. T.

Steel treatment; Process of —. **Steel treatment apparatus.** D. J. Simpson, Assr. to N. S.

Amstutz. U.S.P. (A) 1,351,494 and (u) 1,351,495, 31.8.20. Appl., 5.4.15. Renewed 29.12.19.

(A) STEEL is subjected to a continuously rising heat up to 1370° F. (740° C.) for a carbon content of 0.3% or 1270° F. (680° C.) for 0.65% of carbon; the application of heat is then arrested, the steel

subsequently heated to above the upper critical point, and finally quenched in a gaseous cooling medium. (b) A furnace for carrying out the process is described.—J. W. D.

[Iron-silicon] alloy. J. G. Homan, Assr. to W. H. Keller. U.S.P. 1,352,367, 7.9.20. Appl., 3.1.20.

AN alloy having an electrical resistance higher than that of iron consists of iron with 1–6% Si and 0.2–1% Mn, the amount of manganese added being directly proportional to the silicon content.

—A. R. P.

Silicon-iron alloys; Prevention of graphite precipitation in the manufacture of acid-resistant —. Maschinenfabr. Esslingen. G.P. 321,879, 4.9.18. Addn. to 306,001 (J., 1918, 628A).

THE silicon-iron alloy is melted in such an apparatus, that an increase in the carbon content is prevented, and not in a cupola, as described in the chief patent.—L. A. C.

Arsenious ores; Treatment of —. H. J. Wilson. E.P. 149,366, 3.1.19.

CRUSHED ore containing arsenic is fed by gravity into a roasting furnace through a preheater consisting of a tower having within it a tubular concentric passage through which the volatile products from the furnace pass to the condensing plant. The spent ore from the furnace passes through an air preheater. The impure arsenious oxides obtained are treated in an electro-thermal furnace consisting of a cylinder lined with vitreosil or fused quartz and wound with nickel chromium resistance wire and having a series of annular louvres over which the arsenious oxide is caused to pass; the resublimed oxide passes through the louvres into a central duct in communication with a condensing plant. The whole apparatus is portable and is intended for use at the place where the ore is mined.

—J. W. D.

Metals and metallic articles; Preservation of —. N.C.F. Jensen. E.P. 149,371, 19.2.19.

METALS or metallic articles are immersed in a mixture of mineral lubricating oil with 5% of paraffin, drained, subjected to a temperature of about 300° C. until the surface assumes a greyish tint, and then immersed in a mixture of equal parts of whale oil and mineral lubricating oil.—J. W. D.

Furnaces for melting and refining metals. H. E. Cohen and J. B. Catterall. E.P. 150,024, 22.5.19.

A FLAT-BED flame-heated furnace has at one side one or more doors, a fume-collecting hood adjacent to the doors, and adjustable side collectors, one for each door, adapted to envelop the doors so as to collect the fume and lead it to the hood. In the crown of the furnace is an opening communicating with the main hood.—J. W. D.

Furnace; Metallurgical —. D. E. Griffiths. U.S.P. 1,350,865, 24.8.20. Appl., 21.10.18. Renewed 16.2.20.

A ROTARY furnace has a stationary burner with downwardly directed ports for gaseous fuel and air. A blast-pipe with a number of tuyères extends longitudinally within the wall of the furnace. The rotation of the furnace automatically opens and closes communication between the tuyère openings and the blast-pipe. The walls of the furnace and the burner are cooled.—T. H. Bu.

Smelting-furnace. R. G. and W. R. Ward, Assrs. to Independent Mines Smelting Co. U.S.P. 1,351,451, 31.8.20. Appl., 4.10.16.

A RELATIVELY long chamber has the lower part of its walls curved downwards and inwards to form a furnace-hearth, which is provided with a central

elongated opening having a width greater than its vertical depth. Co-acting burners are arranged below the hearth in opposed pairs, the flames uniting at a point beneath the hearth opening and the concentrated flames being projected through the opening to points considerably above.

—J. W. D.

Electric arc welding. F. J. Heyes. E.P. 150,372, 2.4 and 6.8.19.

AN aluminium rod for electric arc welding of aluminium is provided with a flux consisting of a coating of cryolite or cryolite and salt held in position by aluminium wire, sheet, or gauze, or by means of a light cotton or like fabric. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 6138 of 1909; J., 1910, 161.)—J. W. D.

Ores; Process of treating —. L. B. Skinner. U.S.P. 1,350,286, 17.8.20. Appl., 10.2.19.

A MIXTURE of an oxidised complex zinc ore containing precious metals with an excess of carbonaceous reducing material is charged on to the hearth of a reverberatory furnace, where it is smelted at a temperature of at least 1200° C. The molten matte and supernatant slag produced are protected by a non-oxidising atmosphere, the fume resulting from the reduction and volatilisation of the zinc being led out of the furnace. The treatment is continued until the tapped slag contains not more than 6% Zn.—T. H. Bu.

Metallic oxides; Process and apparatus for reducing —. W. L. Morrison. U.S.P. 1,350,419, 24.8.20. Appl., 22.1.18.

THE oxides in a state of division fine enough to allow them to be carried in suspension by a gas are subjected to the action of hot reducing gases, the reduced metal is precipitated together with slag-forming material, and the metal is subsequently separated from the slag.—J. W. D.

Ores; Apparatus for agglomerating —. E. W. Davis. U.S.P. 1,350,440, 24.8.20. Appl., 19.11.18.

A SERIES of trucks to receive the material to be sintered are mounted on a track. A reciprocating feeding arrangement mounted beside the track engages with one of the trucks automatically upon its forward stroke and passes it by upon its return stroke. During the travel of the trucks an air-tight communication is formed between each truck and an adjacent vacuum chamber.—J. W. D.

Carbonising articles; Process for — and apparatus for same. M. D. Wilbur, F. P. Cannon, and T. J. Murphy. U.S.P. 1,350,483, 24.8.20. Appl., 26.7.17.

THE articles are packed in a non-fusible carbonising material which is quickly raised in temperature and maintained at a predetermined temperature for a certain length of time, an electric current being passed through the articles and the material between electrodes spaced apart from the articles by the carbonising material.—A. G.

Tungsten; Alloying —. J. H. Deppeler, Assr. to Metal and Thermit Corp. U.S.P. 1,350,709, 24.8.20. Appl., 28.10.19.

TUNGSTEN powder is compressed into dense, coherent, self-sustaining tablets, which are added to the alloying metal.—J. W. D.

Metals and alloys; Process of treating —. C. B. Foley. U.S.P. 1,350,714, 24.8.20. Appl., 29.6.17. Renewed 19.1.20.

AN induced electric current is passed through the molten metal and at each locality of heat addition by the current a hydrostatic head is maintained

which exceeds the vapour tension of the mass at the temperature generated. (*Cf.* E.P. 114,851 of 1916; J., 1918, 308 A.)—J. W. D.

Alloy. V. P. Taylor. U.S.P. 1,350,891, 21.8.20. Appl., 4.8.19.

THE alloy contains 80–100 pts. of aluminium, 8–17 pts. of copper, and tungsten.—T. H. Bu.

Zinc alloy. A. Tedesco, Assr. to Soc. Anon. Stabilimenti Biak. U.S.P. 1,350,892, 21.8.20. Appl., 11.7.19.

AN alloy of high strength contains 85–93 Zn, 3–12% Al, and 0.5–4% Sn.—T. H. Bu.

Aluminium alloys; Method for manufacturing —. A. Tedesco, Assr. to Soc. Anon. Stabilimenti Biak. U.S.P. 1,350,893, 21.8.20. Appl., 11.7.19.

ZINC-COPPER-ALUMINIUM alloys containing a high percentage of aluminium are made by separately preparing an alloy containing 66% Zn, 9% Cu, and 25% Al, and adding it to the aluminium bath in amount up to 30% of the final alloy.—T. H. Bu.

Alloy. F. Milliken, Assr. to F. Milliken, S. F. Weaver, and J. M. Repplier. U.S.P. 1,351,673, 31.8.20. Appl., 8.10.19.

AN alloy consists of copper, 41–52%, nickel, 22–28%, and lead, 22–30%.—W. J. W.

Alloys having high mechanical, chemical, and electrical resistance. A. Tedesco, Assr. to Soc. Anon. Stabilimenti Biak. U.S.P. 1,351,811, 7.9.20. Appl., 6.3.19.

AN alloy of the following composition: 35–44% Cu, 1.5–4.75% Fe, 3–6% W, and the remainder Ni. —J. W. D.

Alloy. Z. Jeffries and W. A. Gibson, Assrs. to The Aluminium Castings Co. U.S.P. (a) 1,352,271, and (b) 1,352,272, 7.9.20. Appl., 30.7.19.

AN aluminium alloy containing: 2–5% Cu, 4–25% Zn, and (a) 0.6–1.8% Fe, or (a) 0.5–1.5% Fe with an appreciable amount of magnesium.—A. R. P.

Metallic alloy and method of making same. T. D. Stay, Assr. to The Aluminium Castings Co. U.S.P. 1,352,322, 7.9.20. Appl., 6.3.17.

AN aluminium alloy containing 88–90% Al, 10–12% Cu, and 0.1% Ti, having a low shrinkage, and relatively great hardness, with a fine grain and good bearing qualities, is made by first preparing an alloy of titanium and copper and adding this to the aluminium.—J. W. D.

Aluminium; Process for electrically depositing —. G. L. Williams, Assr. to H. W. Campbell. U.S.P. 1,351,144, 31.8.20. Appl., 11.3.18.

ALUMINIUM is deposited by the electrolysis of aluminium sulphate dissolved in an anhydrous solvent which is normally liquid, and which, while heated, is of higher resistance than the aluminium sulphate to be electrolysed.—J. S. G. T.

Babbitt-metal product, and process of making same. L. Sapery. U.S.P. 1,351,404, 31.8.20. Appl., 21.5.20.

BABBITT-METAL, prior to melting, is coated with a thin film of another metal which has a considerably higher melting point and is without injurious action on the bearing qualities of Babbitt-metal. This film protects the Babbitt-metal from oxidation during melting.—J. W. D.

Magnesium powder; Process for the manufacture of —. D. S. Nicol, Assr. to Shawinigan Electro-Metals Co., Ltd. U.S.P. 1,351,865, 7.9.20. Appl., 23.7.17.

MAGNESIUM, melted in an atmosphere of a gas that

will not combine with it at high temperatures and pressures, is forced into a nitrogen atmosphere, where it is disintegrated into fine particles by means of a nitrogen jet directed into the stream of molten metal.—A. R. P.

Nickel and copper; Method of separating — from copper-nickel matte or materials. R. C. Stanley, Assr. to The International Nickel Co. U.S.P. 1,351,877, 7.9.20. Appl., 5.2.19.

THE copper is partly separated from the nickel compounds of the matte by furnace treatment; the residual nickel-rich material is converted into impure metallic nickel containing an appreciable amount of copper, and pure nickel is recovered from this by electrolytic treatment.—A. R. P.

Nickel-plating. E. N. Todd and W. R. King, Assrs. to The Hanson and Van Winkle Co. U.S.P. 1,352,328, 7.9.20. Appl., 28.12.14. Renewed 12.2.20.

A MIXTURE for electroplating comprises sulphate of nickel and ammonium, with an admixture of gum tragacanth.—J. W. D.

Zinc-bearing ores; Method of treating —. F. K. Cameron, J. A. Cullen and R. W. Hyde, Assrs. to American Smelting and Refining Co. U.S.P. 1,352,399, 7.9.20. Appl., 17.7.17.

THE zinc is converted into sulphate, and an alkali chloride is added in quantity sufficient to transform the zinc sulphate into chloride and to form a double halide salt, which is then crystallised from the solution.—J. W. D.

XI.—ELECTRO-CHEMISTRY.

Nickel resistors; Deterioration of —. F. A. J. Fitzgerald and G. C. Moyer. Trans. Amer. Electrochem. Soc., 1920, 31—34. [Advance copy.]

NICKEL wire employed as a substitute for nichrome as a resistor in electric furnaces was found to have a very short life, the wire becoming very brittle. The deterioration was not due to the action of carbon monoxide, but to that of sulphur. The effect of sulphur is very marked and rapid above 500° C. Nickel wire made brittle by sulphur may be softened by heating in an oxidising atmosphere. The action of sulphur upon nichrome is not so marked as in the case of nickel. If precautions are taken to prevent reaction with sulphur, nickel wire seems to behave satisfactorily as a resistor.

Hydrogen peroxide. Skirrow and Stein. See VII.

Electrical resistivity of refractories. Hartmann and others. See VIII.

PATENTS.

Electrical energy; Transforming the kinetic energy in gases into — and utilising the latter for carrying out gas reactions [e.g., production of nitric oxide]. C. Petersen. E.P. 122,173, 30.12.18.

A STRONG magnetic field is established within the reaction chamber by means of a powerful magnet, and the reacting gases are introduced tangentially. The gases traverse spiral paths, and axial and radial electrodes arranged within the reaction chamber become electrified owing to the ions produced by the motion of the gas in the magnetic field. The electrical energy produced may be utilised for the production of nitric oxide, or for effecting other reactions between the gases passing through the magnetic field.—J. S. G. T.

Electric [rotary] muffle furnace. J. R. C. August. E.P. 149,893, 18.10.19.

A MUFFLE is mounted coaxially within a chamber closed at one end and provided with a central aperture at the other. The annular space separating the muffle from the outer container is divided into an inner and an outer space by a coaxial fire-clay cylinder. An electric heating unit composed of powdered material or a heating coil is placed in the inner annular chamber, and the outer annular space is filled with insulating material. A movable container affording a close fit with the muffle is placed within the latter. The inserted end of the container is closed, and the other end projects a little beyond the outer casing of the furnace and is closed with a removable gas-tight cover. The muffle and outer casing rotate together.

—J. S. G. T.

Furnace; Electric —. J. Thomson. U.S.P. 1,351,977, 7.9.20. Appl., 19.11.19.

An electric furnace is provided with a zigzag

carbon resistor formed of two limbs, the ends of which are connected with carbon terminals which pass out from the heating chamber. The two limbs may be connected in series by means of a metallic conductor connected with carbon terminals outside the furnace chamber.—J. S. G. T.

Furnace; Electric —. F. on Schlegell and W. B. Lewis. U.S.P. 1,352,040, 7.9.20. Appl., 4.4.19.

An electrical contact piece projects through the wall of the furnace below the tap-hole into the melting chamber. The outer end of this contact piece is upturned and provided with a cooling chamber above the portion projecting into the furnace.

—J. S. G. T.

Cathodes; Depolarisation of — in electrolytic cells. P. Venturini. G.P. 322,192, 13.11.15.

JETS of the electrolyte are projected against the cathode surface by compressed air introduced into the bath. The electrolyte is thus maintained at uniform concentration, the cathode freed from hydrogen by oxidation, and the surface of the electrolytically deposited metal maintained clean and in contact with concentrated electrolyte.

—J. S. G. T.

Accumulator plates; Production of a protective coating for the active material used in—.

"Metallatom" G.m.b.H. G.P. 322,250, 31.1.18.

A PROTECTIVE, porous, metallic coating is squirted on to the surface of the plates. This is effected by squirting a mixture of the metal forming the skeleton framework of the plate together with indifferent substances such as kaolin, clay, infusorial earth, ashes, etc., or metals or alloys, which are subsequently rendered inactive or removed.

—J. S. G. T.

Filter electrode and process for making the same.

H. O. Trauns Forschungslaboratorium G.m.b.H. G.P. 322,600, 6.7.18.

THE electrode is constituted of a perforated or slotted cylinder of metal, carbon, or graphite connected with a channel for conveying the electrolyte. The cylinder is surrounded by gauze or a perforated cylinder. Coils of wire may be wound upon the latter, or the outer covering may consist of metal cuttings, "wool," or powder held between cylinders of gauze or perforated plates. The whole is held together with a single nut. In making the electrodes compounds of the heavy metals, insoluble in water, may be introduced into the outer covering and reduced to the metal electrolytically. The electrode affords intimate contact between its large surface and a gaseous, liquid, or emulsified solid electrolyte, with simultaneous thorough mixing with reagents, the electrolyte meanwhile streaming through the porous electrode under the influence of an excess or diminished pressure. The electrode can be used as cathode for purposes of reduction, hydrogenation, etc., or as anode for oxidation or halogenation. It may also be employed in accumulators or galvanic cells.—J. S. G. T.

Zinc battery elements [; Production of — by electro-deposition]. S. O. Cowper-Coles. E.P. 150,597, 8.1.20.

XII.—FATS ; OILS ; WAXES.

Unaponifiable matter; Determination of — and characteristics of bottlenose oil. W. Fahrion. Chem. Umschau, 1920, 27, 131–134, 146–147.

THE author describes a modified method for determining unaponifiable matter in fats. Samples of technical marine animal oils yielded 8–22% of unaponifiable matter, which was identified as cetyl alcohol (m.p. 50° C.), and attributed to the presence of bottlenose oil. A commercial sample of the latter had: Saponif. value, 7.1; iodine value, 86.5; unaponif. matter 37.2%, with iodine value, 61.7. The unaponifiable matter determined by the method of Hönig and Spitz (two extractions of the soap with petroleum spirit) was 38.8%. The fatty acids (60%) remained fluid, and had mol. weight 285.5. They were thus mainly oleic acid; no doeglic acid was found.—C. A. M.

Chinese wood oil; Influence of the free fatty acid content in the valuation of — by the Browne polymerisation test. P. E. Jameson. Analyst, 1920, 45, 328–330.

THE time required to polymerise Chinese wood oil by heat increases with the fatty acid content, and in Browne's method (J., 1912, 731) the presence of 1.9–4.5% of free fatty acid extends the time by 1–2.5 mins. If the oil is mixed with dry calcium hydroxide and filtered, it will then, if genuine, polymerise within 12 mins. when heated at 282° C.—W. P. S.

Wool fat. VII. The "oily acid." I. Lifschütz. Z. physiol. Chem., 1920, 110, 29–40.

THE author's experiments indicate that the acid portion of wool fat contains no oleic acid or other unsaturated fatty acid. After repeated purification, the so-called "oily acid" gives no reaction for oleic acid with chromic and sulphuric acids, and the low iodine value previously ascribed to this "oily acid" probably depends on the presence of an acid formed by the oxidation either of cholesterol or, as the absorption spectrum indicates, of ischolesterol.—T. H. P.

Ultra-filtration. Schmitt. See I.

Colchicum seed oil. Grimme. See XX.

Vulcanised oils. U.S.P. 1,315,246. See XIII.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

Pigments; Diffusing power of —. W. K. Lewis and F. P. Baker. J. Ind. Eng. Chem., 1920, 12, 890–891.

THE diffusion power of a pigment is defined as the weight in g. required to obscure an object behind a suspension of the pigment in a given liquid. A suspension of the pigment, of known concentration, is poured into a vertical cylinder with a plate glass base, and kept uniform by stirring or blowing, until the filament of an incandescence lamp held just below the bottom can no longer be seen. The following results in g. per sq. cm. were obtained with pigments ground in bleached linseed oil:—White lead, 260; carbon black, 2200; lampblack, 1830; red iron oxide, 318; red lead, 137; zinc oxide, 560; whiting, 295; barytes, 170; and lithopone, 560.

—C. A. M.

Turpentine oil; Determination of petroleum spirit in —. A. Allina and H. Salvaterra. Chem.-Zeit., 1920, 44, 673–674, 697–698.

TWENTY c.c. of the sample, 10 c.c. of water, and 20 g. of potassium bromate are placed in a distillation flask and hydrobromic acid (sp. gr. 1.59) is added in small quantities at a time, while the mixture is cooled, until a permanent yellow coloration is obtained. A further quantity of hydrobromic acid is then added, without cooling, so that the total amount introduced is 50 c.c. The mixture is maintained at 40°–50° C. for 1 hr. under a reflux condenser, and then steam-distilled. The distillation is stopped as soon as drops of oil heavier than water come over, the water is separated from the distilled oil, the latter shaken with fuming sulphuric acid, and, after separation of the two layers, the volume of the distilled petroleum spirit is noted. The treatment with sulphuric acid is necessary in order to remove small quantities of brominated terpenes etc. from the distilled petroleum spirit.

PATENTS.

Coating compositions or paints. M. R. Isaacs. E.P. 150,551, 8.10.19.

A WEATHER-RESISTANT water paint is produced by mixing casein or casein glue with lime, together with a fluoride and plaster of Paris; additional materials such as clay, cement, oil, and a preservative such as naphthalene may also be introduced.

—D. F. T.

Gum [resin] from grass trees; Extraction of —. H. J. Pooley and J. L. Strevens. E.P. 150,638, 12.3.20.

THE outside portions of the grass tree (*Xanthorrhoea*) or the crude resins from this source, are extracted with a mixture of benzene and its homologues, boiling below 180° C.; the resin thus obtained contains only relatively small proportions of colouring matter and tannin and is capable of direct application as a raw material for the preparation of substitutes for shellac, and for other industrial purposes.—D. F. T.

Vulcanised oils; Process of treating — and products thereof. W. O. Snelling. U.S.P. 1,315,246, 9.9.19. Appl., 22.5.15.

A VULCANISED oil product, similar in its elastic and plastic properties to gum chicle, is obtained by depolymerising a vulcanised oil and re-polymerising the product to a plastic material without additional vulcanisation. For example, the soft,

plastic product obtained by allowing a mixture of a suitable oil (linseed, castor, soya), an aliphatic alcohol or hydroxy-fatty acid (hydroxystearic acid), and sulphur chloride to solidify, is heated at 100° C. for several hours.—W. H. C.

Varnish for balloons. Ballonhüllen-Ges.m.b.H. G.P. 321,264, 25.1.18.

An oil, e.g., castor oil, is treated with sulphur chloride, the product is dissolved in amyl formate, freed from hydrochloric acid by treatment with an alkali, and added to a balloon varnish, giving a waterproof, airtight, and elastic covering.—L. A. C.

Size. G.P. 321,382. *See* XV.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Coagulation of Hevea latex; Bacteriological study of the —. Denier and Vernet. Caoutchouc et Gutta-Percha, 1920, 17, 10,491—10,493.

EXAMINATION of samples of Hevea latex collected with care for the avoidance of extraneous contamination revealed the presence of micro-organisms of 27 different types, only one of which was anaërobic. Cultures were grown in various media, and observation made of the behaviour of the organisms towards dambosc, lactose, sucrose, milk, albumin, and gelatin. Only one micro-organism was found capable of attacking dambosc (the inositol present in the latex), and this was the only organism invariably present in the samples.

—D. F. T.

Vulcanisation; Application of amino-derivatives of furfural to —. Vulcazone. A. Dubosc. Caoutchouc et Gutta-Percha, 1920, 17, 10,495—10,505.

FURFURAMIDE ("vulcazone"). $C_5H_7O_2N_2$, the condensation product of furfural and ammonia, analogous to hydrobenzamide, is recommended as a catalyst for the vulcanisation process. It is stated to be quite non-poisonous, and the tendency to dissociation into its constituents can be avoided, if necessary, by previously transforming the furfuramide, by the action of heat, into its isomeride furfurine, which is also an effective vulcanisation catalyst.—D. F. T.

Vulcanisation; Theory of the acceleration of —. A. Dubosc. Caoutchouc et Gutta-Percha, 1920, 17, 10,511—10,514.

In the presence of a nitrogenous accelerator during vulcanisation, thiocyanic acid of the formula $H:C:S:N$ is formed, which then undergoes fission into hydrocyanic acid and hexavalent sulphur; the hydrocyanic acid again combines with the free divalent sulphur with formation of thiocyanic acid, and hence of more hexavalent sulphur, this cycle of changes recurring continuously. The hexavalent sulphur, possessing three times as many free valencies as ordinary divalent sulphur, is trebly active as a vulcanising agent.—D. F. T.

PATENTS.

Rubber; Treatment of raw —. Dunlop Rubber Co., J. V. Worthington, and A. W. T. Hyde. E.P. 150,043, 22.5.19.

In order to produce rubber of a uniform degree of softness, thereby avoiding the need for wide variations in the time of "working" on the rolls, the rubber is heated for a suitable time in an inert atmosphere, e.g., of "live" steam. Measurement of the viscosity of the rubber supplies a satisfactory method for the control of the treatment.—D. F. T.

Coated fabric and process of producing the same. J. A. Wilson, Assr. to Duratex Co. U.S.P. 1,352,163, 7.9.20. Appl., 19.12.19.

A WATERPROOF fabric is produced by coating a textile material first with a spreading of rubber, and then with a layer of a vulcanising varnish consisting of a vegetable drying oil mixed with sulphur. The coated fabric is then embossed and vulcanised.—D. F. T.

Waterproofed material; Manufacture of — [using reclaimed rubber]. M. Fränkel und Range, and W. Golombek. E.P. 4451, 20.2.14. Conv., 14.8.13.

See G.P. 278,717 of 1913; J., 1915, 437.

XV.—LEATHER; BONE; HORN; GLUE.

Glutin; Benzene derivatives in — and protein-content of gelatin. E. Salkowski. Z. physiol. Chem., 1920, 109, 32—48.

THE products formed by putrefaction of best commercial gelatin include traces of an indole derivative, about 0.11% of aromatic hydroxy-acids, succinic acid, and at least 1.3% of hydrocinamic acid. The presence of a protein in the gelatin has also been demonstrated. (Cf., J.C.S., i., 684.)—T. H. P.

PATENT.

Size; Manufacture of — from horny material. F. Schmidt. G.P. 321,382, 4.12.17.

A PRODUCT, suitable, e.g., for adding to lime-wash colours, is prepared by heating horny material for a long time in an autoclave above 200° C., with or without the addition of acid or alkaline salts.

—L. A. C.

XVI.—SOILS; FERTILISERS.

Oxidising power of soil from limed and unlimed plots and its relation to other factors. J. R. Neller. Soil Sci., 1920, 10, 29—37.

SAMPLES from plots of loam soil, limed and unlimed, were incubated at 20° C., and examined for bacterial activity by means of carbon dioxide production, ammonia and nitrate accumulation, nitrogen fixation, and bacterial numbers. To determine the amount of carbon dioxide produced, 0.75 g. of soya-bean hay was added to each sample of soil; for the ammonia and nitrate tests 110 mg. of nitrogen as dried blood; and for the fixation of nitrogen, 1% mannitol solution. The moisture content was made up to 50% saturation in each case. The oxidising power of the soil from the limed plots, as judged by the carbon dioxide production, was 40% greater than from the unlimed plots. Ammonia accumulation showed no differences. Nitrate production, nitrogen fixation, and bacterial numbers were all higher in the limed samples. The history of the plots showed that the previous crop production of the plots was closely related to the present oxidising power of the soils in all cases, and less closely to the nitrate accumulation and bacterial numbers, but had no relation to the ammonia accumulation.

—J. H. J.

Acid soil; Effect of dicalcium silicate on an —. B. L. Hartwell and F. R. Pember. Soil Sci., 1920, 10, 57—60.

POT experiments were conducted to trace the effect of commercial dicalcium silicate and hydrated silica on a loam soil growing a crop of lettuce. The two substances were added singly and in combination with limestone and acid phosphate (superphosphate). It was found that the silica compounds could replace limestone in counteracting acid con-

ditions in the soil, but there was no evidence of any specific effect of the silica.—J. H. J.

Calcium in soils; Proposed method for the estimation of total — and the significance of this element in soil fertility. O. M. Shedd. *Soil Sci.*, 1920, 10, 1—14.

THE proposed method is more rapid and accurate than that already in use for the determination of calcium in soils, and one in which the production of a precipitate with ammonia, which occludes calcium, is avoided. After fusing a 1-g. sample with fusion mixture, the silica is separated in the usual manner, the filtrate is made slightly alkaline with ammonia and then just acid with hydrochloric acid, raised to the boil, and precipitated with 1—2 g. of powdered ammonium oxalate. The mixture is allowed to stand on the top of the steam bath for a few hours, and then at room temperature overnight. The precipitate is filtered off and ignited, dissolved in hot dilute hydrochloric acid, and bromine water and ammonia added to precipitate manganese. The solution is acidified with acetic acid, and the manganese is filtered off. The filtrate is then reprecipitated as before. Analyses of a large number of soils, both virgin and cultivated, by this method showed that cultivation led to a considerable loss of calcium. The most fertile soils contained the most calcium. The application of limestone and rock-phosphate to soils poor in calcium is beneficial on account of the calcium they supply as plant food, apart from any other benefit.

—J. H. J.

Calcium and nitrogen content of plants; Relation between the — and the function of calcium. F. W. Parker and E. Truog. *Soil Sci.*, 1920, 10, 49—56.

FROM the consideration of a large number of analyses of various plants with respect to their nitrogen, phosphorus, potassium, calcium, and magnesium content it was observed that calcium was the only element of which the content was closely related to the nitrogen content. The plants examined could be grouped in two classes, according to their calcium:nitrogen ratio. In one class the ratio was low, averaging 0.306, and this class consisted of the grass family, which have a low lime requirement and are tolerant to soil acidity. In the other class the ratio was high, 0.553, and this class contained the legumes and other plants which have a high lime requirement and are sensitive to soil acidity. From these results it may be concluded that plants which have a high protein or nitrogen content, and consequently produce a large amount of acidity from protein metabolism, require a large amount of calcium as carbonate for the neutralisation of plant acids.

—J. H. J.

Barley varieties and fertilisation. J. Ahr and C. Mayer. *Brochure*, Freising, 1919. Biedermann's Zentr., 1920, 49, 334—310.

A RECORD of pot experiments with six varieties of barley, fertilised with lime, potash, phosphoric acid, and nitrogen, singly and in various combinations. Copious supplies of lime, potash, and phosphoric acid were found beneficial in respect of brewing quality and yield of grain, whilst excess of nitrogenous fertiliser proved harmful in both respects, especially when other fertiliser constituents were deficient. Some of the varieties were more injured than others by excess of nitrogen.

—J. H. L.

Ammoniacal nitrogen; Preventing volatilisation of — by means of calcium chloride. A. Stutzer. *Fühling's Landw. Zeit.*, 1919, 68, 59—63. Biedermann's Zentr., 1920, 49, 321—324.

THE volatilisation of ammonia from solutions of

ammonium carbonate, and therefore from stable manure, can be in large measure prevented by addition of calcium chloride, owing to the formation of ammonium chloride and calcium carbonate. About 75% of the ammonia can be fixed in this way, by adding 6 pts. of calcium chloride per 1 pt. of ammoniacal nitrogen present.—J. H. L.

Insecticide tests; Miscellaneous soil —. J. J. Davis. *Soil Sci.*, 1920, 10, 61—72.

THE use of kerosene and coal tar preparations as applications to soils infested with the grubs of beetles, chiefly *Popillia japonica*, gave only moderately successful insecticidal results. Mercuric chloride, sulphuric acid, and acetaldehyde were quite ineffective. A large number of experiments were made with sodium cyanide, which proved to be more efficacious than the others. The granular cyanide was used dissolved in the proportion of 165 lb. per 12,000 galls., which was sufficient for an acre of land, and was applied as a spray from a perforated pipe attached to a tank of the liquid. The treatment had no permanent injurious effect on grass, but corn (maize) crops were appreciably injured. The cyanide disappeared from the soil in 7—10 days, and the addition of ammonium sulphate accelerated its disappearance.—J. H. J.

Seed treatment; Presoak method of —: A means of preventing seed injury due to chemical disinfectants and of increasing germicidal efficiency. H. Braun. *J. Agric. Res.*, 1920, 19, 363—392.

THE use of formalin and copper sulphate for the disinfection of seeds usually causes injury to germination. It was found that if the seeds were saturated with water before applying the disinfectant, then the latter in penetrating the seed was diluted beyond the danger point. It is best to soak the seeds in water for not more than 10 mins., and then to remove them and allow them to remain covered for 6 hrs. The seeds are then soaked in formalin of strength 1:400 or in copper sulphate of strength 1:80 for 10 mins., drained, covered for 6 hrs., and then air-dried. Stimulation of germination was observed in treated seeds. The seeds experimented with were the cereals, but other seeds are amenable to the treatment if the process be modified according to the rate of absorption of water by the seed, its susceptibility to the disinfectant, and the time necessary for the beginning of germination and of the vegetative activity of the infecting organisms.—J. H. J.

Carbon dioxide. Robinson. See VII.

PATENTS.

Sewage sludge; Utilisation of — for the production of manure and other products. G. Young and G. Watson. E.P. 150,375, 29.4.19.

SLUDGE, dried to 50—60% moisture, is placed in a closed furnace of the rotary kiln type and subjected to slow combustion by means of a gentle air draught which is so regulated, in accordance with the moisture in the sludge, as to maintain a low temperature. Such combustion of the non-volatile greases and other organic matter as takes place is complete, without soot formation, but a considerable proportion of organic matter is retained in the ash in a sterilised condition, and the process is conducted so as to produce a porous, easily powdered mass instead of clinker. The volatile oils distilled off during the combustion are led into an ammonia-recovery apparatus, and the ammonium sulphate obtained may be sold separately, or added to the furnace residue with or without other fertilising agents.—W. J. W.

Superphosphate; Process of producing —. C. C. Meigs. U.S.P. 1,351,672, 31.8.20. Appl., 28.10.19.

PHOSPHATE rock is treated with one-half of the

amount of acid used in producing ordinary superphosphate. The product is treated with excess of a solution of an alkali sulphate, and the mass is filtered, and free sulphate removed. The filtrate is crystallised, after which the crystals are heated to at least 100° F. (38° C.) and treated with dilute hydrochloric acid, the solution being then applied to the treatment of phosphate rock, and the resulting product dried.—W. J. W.

Salt mixtures suitable for fertilisers; Process of obtaining — from explosives etc. containing perchlorates. Dynamit-A.-G. G.P. 321,878, 20.9.18.

SALT mixtures free from perchlorates are obtained from explosives or mixtures of salts by extracting the material with solutions of potassium salts, and evaporating the extracts to dryness.—C. A. M.

XVII.—SUGARS ; STARCHES ; GUMS.

Sucrose and some other carbohydrates; Ethylene oxide structure of —. E. F. Armstrong and T. P. Hilditch. Chem. Soc. Trans., 1920, 117, 1086—1090.

FURTHER evidence of the presence of the ethylene oxide form of levulose in sucrose (cf. J., 1920, 127 A) is furnished by the rapid increase in the reducing power to permanganate when sucrose is hydrolysed by means of invertase. When the hydrolysis is carried out by means of hydrochloric acid isomeric change is promoted by the acid, and the figures give little indication of the presence of any more of the ethylene oxide form than is normally produced by acid in a mixture of dextrose and levulose, the ethylene oxide form first produced presumably undergoing rapid rearrangement into the butylene oxide form. Galactose, arabinose, and xylose showed little difference in their behaviour towards permanganate in alkaline solution, but in acid solution the difference was more marked, the pentoses being especially active as reducing agents.—G. F. M.

Dextrose; Optical rotation of — under the influence of hydrochloric or sulphuric acid. I. H. Murschhauser. Biochem. Zeits., 1920, 104, 214—236.

THE influence of acid on the mutarotation of dextrose consists in an acceleration of the reaction, this effect increasing with the concentration of the acid. (Cf. J.C.S., i., 661.)—T. H. P.

Honey; Antiscorbutic value of —. H. K. Faber. J. Biol. Chem., 1920, 43, 113—116.

HONEY appears to have no value as an antiscorbutic, since guinea pigs developed severe scurvy when fed on a diet of oats, water, and honey.—J. C. D.

Starch; Compound of — with phosphoric acid. J. Kerb. Biochem. Zeits., 1919, 100, 3—15.

STARCH was esterified with phosphoric acid by treating a soluble preparation with a solution of phosphorus oxychloride in chloroform in the presence of calcium carbonate. The calcium salt of the amylophosphoric acid was precipitated with alcohol from the concentrated solution and purified. By means of diastatic cleavage hexose monophosphoric acid was obtained from the compound in the form of a calcium salt. The latter substance was fermented by yeast.—S. S. Z.

Ultra-filtration. Schmitt. See 1.

PATENTS.

Starch and conversion products thereof; Method of manufacturing —, and improved products obtained therefrom. A. W. H. Lenders. E.P. 149,374, 5.3.19.

STARCH prepared by known methods is freed from residual proteins by the action of bacteria, such as *B. putrificus*, which render the proteins soluble without affecting the starch appreciably; the dissolved proteins are then removed by washing. Starch thus purified can be converted, without loss, into dry, finely divided dextrose, free from colour or bitter flavour, by hydrolysing with acid, concentrating to a syrup, heating the latter to the consistency of whipped cream, and allowing it to crystallise.—J. H. L.

Sugar boiling; Process of — [for production of toffee]. Ballochmyle Creamery Co., Ltd., and R. McCrone. E.P. 150,588, 18.12.19.

Saccharic and tartaric acids. E.P. 108,494. See XX.

XVIII.—FERMENTATION INDUSTRIES.

Amylase; Process of purifying pancreatic —. H. C. Sherman, I. D. Garard, and V. K. La Mer. J. Amer. Chem. Soc., 1920, 42, 1900—1907.

A FURTHER study of the process of purification of pancreatic amylase previously described (J., 1911, 973; 1920, 37 A), determinations of the total solids and enzyme activity being made at each stage. Alcohol up to 5% or an alcohol-ether mixture up to 8% of the volume of the substrate did not materially affect the activity of the amylase. In the process of purification used about 50% of the amylolytic activity was lost by the end of the dialysis, but in another series of experiments, using liquid air cooling in the later stages, it was possible considerably to increase the proportion of active amylase recovered in the final product. The precipitate ("sac precipitate") which formed in the inner solution during dialysis showed very high proteolytic and little or no amylolytic activity. (Cf. J.C.S., Nov.)—W. G.

Alcoholic fermentation; Relation of aldehydes to —. C. Neuberg and M. Ehrlich. Biochem. Zeits., 1920, 101, 236—276.

THE influence of 71 aldehydes on alcoholic fermentation was tried. It was found that the stimulating effect of the aldehyde group was general and independent of the radical associated with it. This activation takes place whether the fermentation is produced by living yeast or by the cell-free juice.—S. S. Z.

Alcoholic fermentation; Relation of phytochemically reducible substances to the process of — and the nature of the action of activators. C. Neuberg and M. Ehrlich. Biochem. Zeits., 1920, 101, 276—319.

NUMEROUS experiments are described which show that most ketones and their derivatives and phytochemically reducible substances are capable of activating alcoholic fermentation. The activating influence is not so marked—in fact, almost absent—with the lower ketones.—S. S. Z.

Enzymes; Chemical nature of —. T. Bokorny. Biochem. Zeits., 1919, 100, 100—114.

THE alkylamino-nitrogen was estimated in a number of well-known enzymes by means of nitrous acid. The amino-nitrogen was found to vary from 3.05% in rennet to 7.66% in papayotin. The author considers that the results obtained are in favour of the theory of the protein nature of enzymes.—S. S. Z.

Yeast cell; Influence of surface-active nonylic acid and of some surface active homologues of the alcohol series (amyl alcohol and octyl alcohol) on the — and on fermentation. W. Windisch, W. Henneberg, and W. Dietrich. *Biochem. Zeits.*, 1920, 107, 172—191.

A CONCENTRATION of 0.005–0.02 of nonylic acid has an inhibitive action on yeast fermentation; 0.017–0.04 of octyl alcohol has a similar effect. Higher concentrations of amyl alcohol are required to inhibit fermentation. Nonylic acid and octyl alcohol also produce a diseased condition of the yeast cell accompanied by alteration of its appearance and production of fat in the cell. The experiments point to the fact that the influence of these substances is not due to their chemical properties but to their surface action.—S. S. Z.

Isoamyl alcohol; Preparation of — by Pasteur's method. F. Martin. *J. Pharm. Chim.*, 1920, 22, 220—226.

Is the preparation of the amylsulphuric acids, which is the first step in the isolation of pure isoamyl alcohol from fusel oil by the fractional crystallisation of the barium amylsulphates, the best results are obtained with 90–91% sulphuric acid (sp. gr. 1.820–1.825), using an excess of 15–20% above the theoretical quantity. Under these conditions about 60% of the alcohol is esterified, whilst if a very large excess of acid is used, considerable difficulties are encountered later in the separation of the barium sulphate without any adequate compensation in the increased percentage of alcohol esterified. A small proportion of the alcohol is apparently converted into the neutral sulphate, the actual yield of the acid sulphates amounting to 50–55%.—G. F. M.

Distillation and rectification. L. Gay. *Chim. et Ind.*, 1920, 4, 178—188.

THE author gives equations for calculating the composition of the liquid and vapour phases in the distillation and rectification of a mixture of two constituents, and for determining the minimum amount of heat necessary. In the case of aqueous alcoholic solutions, if the strength exceeds 8.2% by weight of alcohol, the heat required varies little with the concentration of the solution, and ranges from 900,000 to 1,000,000 cal. per 1000 kg. of alcohol (95%) recovered. With these solutions the height of the rectifying column may be kept unaltered with a theoretical minimum of 25 sections. On the other hand, the height of the distillation column should be decreased as the strength of the solution increases up to 40%; above this concentration it should be increased slightly as the percentage of alcohol increases. Thus, compared with the rectifying column, the height of the distillation column is equal at 8.2% ; half at 10% ; three-tenths at 40% ; and three-sevenths at 83%. With concentrations below 8.2% , the requisite height of distillation column governs the minimum heat supply. As the alcohol content decreases from 8.2%, the rectification column should be correspondingly reduced. At 3.7% its length will be $\frac{1}{4}$ of that of the distillation column. In practice theoretical data are modified by plant imperfections, and correction tables should be drawn up, giving for each metre of the column the equivalent theoretical number of plates. Proposed schemes for confining the heat supply to the plates of the distillation column and the cooling to the rectifying column or, in another case, for causing the emergent liquid to recirculate through the upper sections, are considered to be unsound. A greater efficiency of the plates, however, should be aimed at.—W. J. W.

PATENTS.

Acetone and butyl alcohols; Fermentation processes for the production of —. C. Weizmann. E.P. 149,355, 21.2.16.

UNHOPPED brewers' or distillers' wort, of low gravity, is sterilised by heating under pressure and fermented by the bacteria previously described (E.P. 4845/15; J., 1919, 301 A). The concentration of carbohydrates in the wort may vary from 4 to 9% , but in these cases the acidity must not exceed 0.4–0.6%. The ordinary brewery or distillery plant may be employed, with such modifications as are necessary to exclude infection during the cooling and fermentation of the wort.—J. H. L.

Yeast; Manufacture of — from fermented musts, and more particularly the fermented musts of molasses and sugar beet pulp. L.J.P.M.J. Dupire. E.P. 149,438, 13.5.19.

WHERE the production of yeast is the chief aim of fermentation the worts are diluted to such an extent (e.g., to sp. gr. 1.030 in the case of molasses or sugar beet worts) as to limit the amount of sugar present to that required for yeast growth. The yeast is subsequently separated by centrifuging (cf. E.P. 123,711; J., 1919, 334 A). Molasses worts of sp. gr. 1.030 give practically as much yeast as those of sp. gr. 1.090.—J. H. L.

Yeast; Process of treating waste brewers' — to render it suitable for baking purposes. H. W. Andersehou. E.P. 149,533, 5.9.19.

BREWERS' yeast is treated first with a solution of sodium bicarbonate and a small quantity of sodium salicylate, and afterwards with a solution of borax. It is next preferably treated with a cleansing agent (sodium chloride and potassium carbonate), then aerated in presence of nutrient salts, cane sugar, pepsin, and infusion of willow, and finally mixed with cream of tartar, potato-flour, and dried milk powder, and pressed.—J. H. L.

Alcohol; Absolute — and process of making the same. G. B. Frankforter. U.S.P. 1,350,254, 17.8.20. Appl., 20.12.18.

ORDINARY commercial alcohol is partially dehydrated by treatment with a mixture of potassium carbonate and potassium fluoride, then decanted from the mixture and heated with quicklime in an autoclave under a pressure of 55 lb. per sq. in., and finally the last traces of water are removed by distilling and passing the vapours over calcium carbide.—J. H. L.

Liquids; Process of de-alcoholising —. Apparatus for treating liquids. W. Koedding and W. J. Lemp. U.S.P. (A) 1,351,521 and (a) 1,351,522, 31.8.20. Appl., 21.2 and 14.4.17.

(A) BEER is heated in a pipe system and then passed in a continuous stream through a vacuum chamber at a temperature sufficient to evaporate the alcohol without impairing the other constituents. (a) Liquids are evaporated in a tank heated by means of a water-jacket and having upon the wall opposite to the jacket a helical V-shaped trough. Means for delivering liquid into the upper and removing it from the lower part of the tank are provided, and the vessel is connected with a suction system within which is a surface condenser.

—C. A. M.

XIXA.—FOODS.

Cereals; Ripening of —. H. Lüers. *Biochem. Zeits.*, 1920, 104, 30—81.

THE author has devised a new method of estimating acidity in organic extracts and an improvement in Sørensen's formol-titration method (*cf.* J., 1920, 669 A), and has applied both of these to follow the alterations in acidity, formol-titratable nitrogen, and enzymic relations of barley, wheat, oats, and rye during the final stages of ripening and subsequent storage for two months. (*Cf.* J.C.S., Nov.)

Antiseptic action of some chlorine derivatives of methane, ethane, and ethylene. E. Salkowski. *Biochem. Zeits.*, 1920, 107, 191—202.

THE suitability as preservatives of methyl chloride,

chloroform, methylene chloride, acetylene dichloride, trichloroethylene, and ethyl chloride was tested. Trichloroethylene on account of low cost, of the small quantities required to be employed, and of its volatile character was found to be the most suitable.—S. S. Z. ●

Silver; Oligodynamies of —. II. R. Doerr. *Biochem. Zeits.*, 1920, 107, 207—219.

THE bactericidal action of metallic silver disappears when the metal is ignited, boiled several times with distilled water, or is embedded in an agar jelly. The inactivated metal can be re-activated by being treated with very dilute solutions of a strongly dissociated acid. The oligodynamic principle of silver is dialysable and shows the same properties of diffusion in agar jellies as silver oxide and silver nitrate. Bacteria seeded on an agar plate containing metallic silver, silver oxide, and silver nitrate grow often in two concentric rings similar to the Liesegang phenomenon. Pieces of silver embedded in a blood-agar plate produce hæmolytic zones.—S. S. Z.

PATENTS.

Sewage sludge or other wet or moisture-laden material; Method of and means for drying —. L. Linden. E.P. 150,368, 25.2.19.

IN the upper part of an enclosed structure are arranged a number of horizontal or inclined troughs provided with mechanical stirring devices; below each pair of troughs is a drying floor divided into separately-hinged sections. A second series of troughs and floors may be placed beneath the first. Below these may be arranged hoppers from which the material passes to grinding rollers and then on to a bottom floor, which may be heated, and from which the material may pass to a conveyor. At the base of the structure are lateral air inlets, supplemented if required by others near the top, and in the roof are air outlets, near which fans may be fixed to facilitate removal of moisture-laden air. The partly-dried sludge is introduced by means of distributors into the top troughs in which it is aerated and dried by a current of air, heated by radiators at the base. Gangways for workers, placed between the troughs, serve at the same time as baffles for the air current. When the material in the troughs has assumed a granular condition, a further quantity of partly-dried sludge is mixed with it, together with disinfectant if desired, and the excess material is then expelled by the stirrers on to the floor below, whence, after a suitable period, it is tilted on to the next series of troughs and floors, from which it finally passes to the hoppers and delivery floor.—W. J. W.

Sewage sludge. E.P. 150,375. *See* XVI.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Codeine; Determination of —. H. E. Annett and H. Sen. *Analyst*, 1920, 45, 321—328.

TEN g. of dry opium, or a suitable quantity of other substance (*e.g.*, alkaloids, plant material, etc.), is mixed with 4 g. of calcium hydroxide with the gradual addition of 100 c.c. of water; the mixture is stirred for 30 mins., filtered, 50 c.c. of the filtrate is treated with 40 c.c. of 2% acetic acid and 10 c.c. of basic lead acetate solution (*sp. gr.* 1.25), filtered, 75 c.c. of the filtrate is treated with 2.5 g. of calcium

hydroxide, the mixture shaken for 30 mins., filtered, and 50 c.c. of the filtrate extracted with three successive quantities (50 c.c. each) of toluene. The united extracts are filtered and dry gaseous hydrogen chloride is introduced in slight excess; this excess is removed by a current of air, the precipitated codeine hydrochloride is collected on a filter, dissolved in a small quantity of water, the solution evaporated, and the residue dried and weighed. If the treatment with basic lead acetate is omitted, the codeine hydrochloride obtained is highly coloured, but the error introduced is not more than 5–10%.—W. P. S.

Colchicum seeds; Alkaloidal content and fatty oil of —. C. Grimme. Pharm. Zentralh., 1920, 61, 521–524.

SPEAKING generally, the colchicine content (0.11–0.52%) in colchicum seeds is smaller the higher the relative weight of 1000 of the seeds. A sample of powdered seeds, extracted with ether, yielded 17.6% of a light brown odourless oil with the following characters: Sp. gr. (15° C.), 0.9176; solidif. p., –9° C.; n_D^{20} = 1.4642; acid value, 20.32; saponif. value, 184.3; iodine value, 128.5; unsaponif. matter, 0.71%. *Fatty acids*: m.p., 24.0° C.; solidif. p., 22.5° C.; neutralisation value, 187.6; iodine value, 131.0; and mean molec. equiv., 300.3.—C. A. M.

Digitalis; Some of the important constituents of —. W. J. McGill. J. Amer. Chem. Soc., 1920, 42, 1893–1900.

With careful manipulation and uniform methods of procedure, using various solvents, it is possible to obtain crude fractions from digitalis which will have a reasonably constant chemical composition, but in view of the difficulty of separating individual glucosides in a chemically pure state from these crude fractions, it does not appear that such an undertaking has at present any commercial value. The cold water extract of digitalis leaves contains, at the most, only a very minute quantity of digitoxin, its activity being entirely due to a chloroform-soluble and chloroform-insoluble fraction. Digitasaponin from the leaves is entirely inactive and non-haemolytic when purified. The chloroform-soluble fraction from the hot water infusion of the leaves is a mixture of gitalin and digitoxin.—W. G.

Halogenation; Experiments on —. Direct displacement of negative groups by halogen in the aromatic series. I. Displacement of the nitro-group by bromine. S. N. Dhar. Chem. Soc. Trans., 1920, 117, 993–1001.

THE interaction between bromine and aromatic nitro-compounds at 200°–250° C., under pressure, results as a rule in the displacement of the nitro-groups, and, sufficient bromine being present, in further halogenation, to an extent, in some cases, beyond what is possible by direct halogenation under any other known conditions, the best example of this being the formation of octabromoxanthone from tetrabromodinitroxanthone. It is assumed that in the reaction a more powerful halogenating agent than the bromine itself is formed, possibly in accordance with the equations:

In the case of nitrophenols an excess of bromine results in the displacement of the hydroxyl group as well, picric acid giving, for example, a mixture of tetra- and pentabromophenol and hexabromobenzene. 2,4,6-Trinitrotoluene gives pentabromobenzyl bromide, whilst various tetrabromonaphthalenes and hexabromonaphthalenes were obtained from 1,5- and 1,8-dinitronaphthalene. The xanthone and coumarin series supplied examples of particularly stable nitro-groups which could not be displaced by bromine under the experimental conditions studied.—G. F. M.

Gallie acid; Derivatives of —. I. Synthesis of 4-hydroxy-3,5-dimethoxyphthalic acid. R. L. Alimchandani and A. N. Meldrum. Chem. Soc. Trans., 1920, 117, 961–970.

GALLIC acid trimethyl ether was condensed with chloral in presence of sulphuric acid with the formation of a trichloromethylphthalide, indicating that the 4-methoxyl group of the ether was first hydrolysed by the acid, with formation of syringic acid. Somewhat better results were obtained by using syringic acid (4-hydroxy-3,5-dimethoxybenzoic acid) for the condensation, the latter being conveniently obtained from the above gallic acid trimethyl ether by preliminary treatment with 96–98% sulphuric acid. On hydrolysis the trichloromethylphthalide gave the corresponding carboxylic acid which on heating lost carbon dioxide with the formation of 4-hydroxy-3,5-dimethoxyphthalide. This on methylation and oxidation gave 3,4,5-trimethoxyphthalic acid. This acid readily gave an anhydride which lost a methoxyl group on treatment with sulphuric acid in the cold with the formation of 4-hydroxy-3,5-dimethoxyphthalic acid. Both these phthalic acids on boiling with hydrochloric acid are reconverted into the corresponding gallic acid derivative with loss of carbon dioxide.—G. F. M.

Dichloroethyl sulphide [“mustard gas”]; Properties of —. F. Martin. J. Pharm. Chim., 1920, 22, 161–165.

LIQUID dichloroethyl sulphide is heavier than water; its alcoholic solution when mixed with a large volume of water yields a white turbidity which disappears after some time. When it is boiled with alcoholic potassium hydroxide solution the vapours produced give a white precipitate on contact with Deniges' reagent (acid mercuric sulphate solution). If the vapours are passed into iodine solution an odour resembling that of mercaptan is noticed. The substance is hydrolysed fairly rapidly by water; its aqueous solution gives a white precipitate (di-iododiethyl sulphide) with Grignard and Rivat's reagent (sodium iodide, 8, copper sulphate, 0.8 g., gum arabic solution, 1, and water, 33 c.c.).—W. P. S.

Organic acids; Dissociation constants of — as means for their identification. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 514–518.

THE hydrogen ion concentration of a solution of a weak organic acid, and hence the dissociation constant, may be conveniently determined colorimetrically by observing the colour change of a suitable indicator in the solution and in a solution of known hydrogen ion concentration. A selection of indicators suitable for various weak acids is given. Standard solutions of known p_H values for comparison may be prepared from dilute hydrochloric acid or from mixtures of potassium hydrogen phthalate with hydrochloric acid or sodium hydroxide.—W. S. M.

p-Cymene as a solvent. A. S. Wheeler. J. Amer. Chem. Soc., 1920, 42, 1842–1846.

*p-CYME*NE is the principal constituent of so-called spruce turpentine, a by-product of the manufacture of sulphite pulp, and may be obtained from it by the following process. Air is bubbled through the turpentine for 10 hrs. to remove sulphur dioxide. The liquid is then distilled with superheated steam in an apparatus so arranged that the vapours pass first through a 30% solution of sodium hydroxide and then into the condenser. The distillate is purified by shaking it with a 5% solution of sodium hydroxide and then distilling it over sodium. So prepared *p*-cymene has b.p. 176°–176.5° C., n_D^{20} = 1.4905, and only very slowly develops a yellow colour when a trace of *p*-anisidine is added and the

mixture exposed to light. Under similar conditions an impure sample develops a red colour. The solubilities of a considerable number of organic compounds in this solvent are tabulated.—W. G.

Terpin; Quantitative estimation of —. O. Fernández and N. Luengo. *Anal. Fis. Quim.*, 1920, 18, 158—165.

On treatment with acetic anhydride and anhydrous sodium acetate, only one of the two hydroxyl groups of terpin is acetylated; but when a solution of terpin in oil of turpentine is treated in like manner, complete acetylation is achieved. (*Cf. J.C.S.*, Nov.)—W. R. S.

Eucalyptol determination. C. T. Bennett and M. S. Salamon. *Perf. Essent. Oil Rec.*, 1920, 11, 302.

The results of numerous trials indicate that the cresol method (Cocking, J., 1920, 610 A) is no more reliable than the official phosphoric acid method for the estimation of eucalyptol, as the constituents of eucalyptus oil other than eucalyptol have a marked influence on the melting point of the cresol compound.—G. F. M.

Ether-air mixtures; Self-ignition of —. J. A. McClelland and H. V. Gill. *Sci. Proc. Roy. Dublin Soc.*, 1920, 16, 109—119.

IGNITION occurs when a mixture of ether vapour and air is allowed to rush into a partially evacuated tube. Measurements of the temperature in the tube showed that the rise of temperature produced reached the ignition point of the mixture. The rise of temperature is attributed to the conversion of the translational energy of the gas rushing into the tube into heat. The length of the explosion tube affects the results.—J. R. P.

Pharmacology of selenium and tellurium. I. Action of their acids on bacteria. G. Joachimoglu. *Biochem. Zeits.*, 1920, 107, 300—313.

THE IONS of tellurous and selenious acids are much more active than those of telluric and selenic acids. The growth of moulds is hardly affected by the action of tellurites and tellurates. Bacteria, especially of the typhus-coli group, are, on the other hand, very sensitive to the action of these substances. The author suggests the application of tellurium compounds in the chemotherapy of typhoid infection.—S. S. Z.

Isoamyl alcohol. Martin. *See* XVIII.

Weak acids and bases. Kolthoff. *See* XXIII.

PATENTS.

Saccharic and tartaric acids; Production of — from carbohydrates. Diamalt-A.-G. E.P. 108,494, 4.8.17. Conv., 4.8.16.

SACCHARIC and tartaric acids are readily obtained by oxidising carbohydrates at 100° C. in presence of oxidising catalysts, particularly molybdenum, mercury, or platinum, by means of sulphuric and nitric acids, or sulphuric acid and oxides of nitrogen, peroxidised by treatment with oxygen, ozone, or air. For example, 100 pts. of starch is mixed with 150 pts. of water and 3 pts. of sulphuric acid, and saccharified. Concentrated sulphuric acid (25 pts.), nitric acid of sp. gr. 1.4 (60 pts.), and an oxide of molybdenum (1 pt.) are then added, and the whole is maintained at 100° C., a further 100—140 pts. of nitric acid being added during the course of the reaction. At the end of the operation the nitric acid is evaporated, and after diluting the residual liquor with water, the molybdenum is precipitated by hydrogen sulphide, and the sulphuric and traces of oxalic acid by lime or baryta, and saccharic acid separated from the filtrate after

concentration as potassium hydrogen saccharate. The yield is 65%. If mercury is used as catalyst and twice as much nitric acid is added, a yield of 60% of potassium hydrogen tartrate, together with about 10% of saccharate, is obtained.—G. F. M.

Acetic acid from acetylene as primary material; Catalytic processes for preparing —. Soc. des Acieries et Forges de Firminy. E.P. 132,529, 18.2.19. Conv., 13.3.18.

THE vapours of acetaldehyde produced by the catalytic hydration of acetylene (E.P. 124,194; J., 1920, 582 A) are absorbed from the gaseous current by means of a 15—20% solution of sulphuric acid at 20° C., which polymerises the aldehyde to paraldehyde. The latter is separated from the acid and is depolymerised by boiling with 30—50% sulphuric acid and converted into acetic acid by the action of air or oxygen in presence of copper permanganate or a mixture of copper and manganese acetates. The object of the temporary polymerisation of the aldehyde is to attain a better recovery of the product from the reaction gases by conversion into the less volatile and more easily handled paraldehyde, and it also enables the material to be temporarily stored without risk in the event of a breakdown of the oxidising plant. The hydration, polymerisation, depolymerisation, and oxidation reactions are conveniently carried out in a series of five sandstone towers which are traversed from the bottom upwards by the reacting gases in counter-current with the liquid reagents. The first tower is used only for removing the excess aldehyde from the spent hydrating catalyst previous to its electrolytic regeneration, and each of the remaining towers serves for one of the four reactions above mentioned.—G. F. M.

2-Phenylquinoline-4-carboxylic acid; Manufacture of the allyl ester of —. O. Imray. *From Soc. of Chem. Ind. in Basle.* E.P. 150,401, 28.5.19.

THE allyl ester of 2-phenylquinoline-4-carboxylic acid is, like the alkyl esters, tasteless, and has the further advantage of dissolving uric acid more readily than either the alkyl esters or the acid itself. It may be prepared by any of the usual methods of esterification, such as the action of an allyl halide on a salt of the acid, or by the action of allyl alcohol on the acid chloride or on the acid itself in presence of hydrogen chloride or sulphuric acid. The ester boils at 260° C. under 15 mm. pressure, and melts at 30° C. Its hydrochloride crystallises from alcohol in small citron-yellow needles, m.p. 145°—147° C.—G. F. M.

Nitro-compounds; Reduction of aromatic —. J. Tcherniac and S. H. Davies. E.P. 150,412, 29.5.19.

AROMATIC nitro-compounds, particularly hydroxy-nitro-compounds, are reduced by treatment with a mixture of hydriodic and hydrochloric acids. The consumption of iodine may be reduced to a minimum by adding a substance, such as phosphorus, which in presence of water re-converts the liberated iodine into hydriodic acid. An example is given of the reduction of *p*-nitrophenol by boiling 139 pts. with 36 of amorphous phosphorus, 13.9 of iodine, and 180 of 20% hydrochloric acid under a reflux condenser. The reaction is completed when iodine vapour appears in the condenser.—G. F. M.

Thienylquinolinecarboxylic acids. M. Hartmann and E. Wybert. Assignors to Soc. of Chem. Ind. in Basle. U.S.P. 1,350,408, 24.8.20. Appl., 21.10.18.

2-THIENYLQUINOLINE-4-CARBOXYLIC acids, obtained by condensing isatin compounds with acetothienone, are crystalline compounds of definite melting point. They are soluble in most organic solvents and in strong mineral acids, and are of value for histological and therapeutical purposes.—G. F. M.

Desoxycholic acid; Process of obtaining —. H. Wieland. G.P. 321,726, 10.8.16.

Desoxycholic acid is precipitated as an alkaline salt from its solution in strong alcohol.—C. A. M.

Carbamides [ureas]; Method for producing asymmetric —. A. V. Blom. U.S.P. 1,351,888, 7.9.20. Appl., 3.4.19.

SEE E.P. 125,581 of 1919; J., 1920, 582 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic emulsions; Size and sensitiveness of the grains in —. T. Svedberg. Z. wiss. Phot., 1920, 20, 36—50.

IN considering the blackening-law (*Schwarzungsgesetz*) of a photographic plate and the behaviour of the individual grains contained in it, the view that the law is a consequence of the lack of uniformity of the photo-chemical light-field inside the film is negated by the work of Luppo-Cramer, Scheffer, and others, and by the author's own experiments with very thinly coated plates for which the usual type of characteristic curve was obtained. The possibility that each grain obeys the law of the plate appears to be inadmissible, since the size of grain resulting by development appears to be dependent on the amount of development and not on the exposure. In experimental examination of the two remaining possibilities, viz., that each class of grains of approximately equal sizes obeys its own law, or that only an emulsion with grains of varying sizes obeys the law, uniform thin coatings of very dilute emulsions were used; after exposure and development the plates were treated with a silver solvent (acid potassium permanganate solution or acid potassium bichromate solution) and photomicrographs of the resulting films taken with a linear magnification of 1000. Prints of the micrographs were made with a further magnification of 4 and the grains for a definite area of each print counted and assorted into 4 classes of size with the aid of a screen ruled in sq. mm. The grains counted in this way are of course those which are not developed, and the numbers and sizes of the developed grains have to be obtained by comparison with the same emulsion untreated. Tables and curves are given for one type of plate, showing the relationship between exposure and percentage of grains affected in the 4 size-classes, and between size of grain and the percentage number attacked; the curve for the former is similar to the usual characteristic curve and that for the latter to an exponential. Similar results are given for solarisation exposures, for hydrogen peroxide effect and for ordinary chemical fog, and the results are all in general agreement with the view that the larger grains are the more sensitive.—B. V. S.

Photographic printing process without silver bromide. K. Wilcke. Phot. Korr., 1920, 57, 173—175. Chem. Zentr., 1920, 91, IV., 380.

THE process depends on the increase of electrical conductivity of selenium on exposure to light. A glass plate, provided with an excessively thin coating of gold or platinum, is placed in intimate contact with a thin sheet of selenium. In contact with the other side of the selenium is placed a sheet of paper soaked in a solution of some substance, such as potassium ferrocyanide, which gives a coloured substance on passage of an electric current; the paper is backed up by a metal plate. When the glass side of the system is exposed in a camera, an electric potential difference being applied to the gold or platinum film on one side and the metal

plate on the other side, a reproduction is obtained on the paper.—B. V. S.

PATENT.

Celluloid films. U.S.P. 1,352,216. See V.

XXII.—EXPLOSIVES; MATCHES.

Nitroglycerin; Application of Devarda's method to the determination of nitrogen in —. Kochler, Marquoyrol, and Jovinet. Ann. Chim. Analyt., 1920, 2, 271—272.

ABOUT 0.5 g. of nitroglycerin is placed in a flask together with 40 c.c. of hydrogen peroxide (12 vol.) and 6 c.c. of potassium hydroxide solution (sp. gr. 1.4), the mixture is agitated by a mechanical stirrer (1500 revs. per min.) and heated gradually to 40° C. After 40 mins., the walls of the flask are rinsed down with a few c.c. of alcohol and the heating continued at 70° C. for a short time. The saponification is thus completed and the nitrate in the solution is reduced in the usual way with Devarda's alloy (J., 1893, 550), the resulting ammonia being determined by distillation.—W. P. S.

"Brisance" of explosives; Measurement of the —. H. Kast. Z. ges. Schiess- und Sprengstoffw., 1920, 15, 171—173, 181—184.

THE Trauzl lead block test, although it gives results having a definite relationship to the calculated specific pressure for the same classes of explosive, takes no account of density or of the time factor. Tables are given showing the figures for specific volume, explosion temperature, solid residue, specific pressure, and lead block tests, for various explosives, as well as the effect of density on the lead block expansion. The nature of the casting, and the temperature during the test also exert an influence on the results. The causes of the discrepancies between practical results and energy calculated from the formula $t = p_0 v_0 t / 273(1 - a)$ are discussed. The author gives equations representing the decomposition of a series of explosives, together with the calculated values for Q , Q_0 , t , i , and v_0 . In contrast with the Trauzl block, the lead crusher test (Kast, Z. ges. Schiess- u. Sprengstoffw., 1913, 8, 88) provides a more accurate means of determining the energy of explosives in that it takes into account the density and velocity of detonation. It has the disadvantage of being inapplicable to explosives which are not easily detonated. Comparative results obtained with the lead block and the lead crusher with trinitrotoluene and ammonium nitrate mixtures are tabulated, and a table showing lead-crusher tests in relation to density, velocity of detonation, specific pressure, and the calculated brisance is appended.—W. J. W.

Military explosives; Strength and velocity of detonation of various —. W. C. Cope. J. Ind. Eng. Chem., 1920, 12, 871—873.

TEN grms. of TNT is fired in a standard mortar, and then by means of trial shots the weight of the explosive under test which will deflect the mortar by an approximately equal number of ballistic degrees is determined. A table of the TNT values of the most common explosives is given. The velocities of detonation of various explosives under definite conditions of density and confinement are tabulated. Tetryl had a velocity of 5450 m. per sec., as compared with 4600 m. per sec. for TNT. Coarse ammonium nitrate has no deleterious effect on the velocity of amatol, especially in the presence of 55% of TNT. Fragmentation tests, in which the number and sizes of the fragments resulting from detonation in steel shells were measured, showed that in this respect TNT was superior to a mixture of TNT and ammonium nitrate or of TNT, tri-

nitroxyline, and ammonium nitrate, although inferior in strength.—C. A. M.

After-corrosion in the bores of firearms; Cause and prevention of —. W. J. Huff. *J. Ind. Eng. Chem.*, 1920, 12, 862—870.

THE present high-pressure smokeless cartridges leave no nitrocellulose or corrosive acid residue. After-corrosion is due to the deposition of water-soluble salts (e.g., potassium chloride from the primer), with subsequent exposure to excessive humidity in presence of oxygen. These salts are retained in pitholes in the boring, and cannot be mechanically removed. After-corrosion may be prevented by tightly closing both ends of the bore after firing. The present U.S.A. service ammunition may be rendered non-corrosive by eliminating potassium chlorate from the primer. A simple method of testing cleaning compositions is described. Corrosion from nitrocellulose powder probably only occurs when the confining pressure is very low.—C. A. M.

PATENTS.

Explosive powder; Perforated pellets of — and process of making same. F. I. and E. du Pont. U.S.P. 1,352,121, 7.9.20. Appl., 12.6.18.

EXPLOSIVE pellets are made from black powder dust formed into masses by means of collodion.—W. J. W.

Fertilisers from explosives. G.P. 321,878. See XVI.

XXIII.—ANALYSIS.

Indicator; A polychromatic —. J. Moir. *J. S. Afr. Assoc. Anal. Chem.*, 1920, 3, 6—8.

THE indicator is 3,3'-dihydroxybenzaurine-2"-sulphonic acid (catecholsulphonphthalein), and is prepared by condensing catechol with *o*-sulphobenzoic acid. It shows the following range of colours in acid and alkaline solutions:—Strong acid, purple-pink; N/10 acid, orange; N/40 acid, yellow; neutral, colourless or very faint green; just alkaline, violet; dilute alkaline, indigo-blue; strong alkaline, grass-green.—W. P. S.

Hydrogen-ion concentration of some standard solutions at various temperatures. L. E. Walbum. *Biochem. Zeits.*, 1920, 107, 219—229.

THE H-ion concentration of mixtures of glycine and sodium hydroxide, borate and hydrochloric acid, borate and sodium hydroxide increases with increased temperature between 10° and 70° C. The reverse is the case with a citrate and sodium hydroxide mixture. In the former three mixtures the alteration is more marked in the alkaline mixtures and diminishes with diminution of the alkalinity of the mixtures.—S. S. Z.

Analysis; Apparatus for evolution methods of —. [Determination of sulphur and carbon in steel.] E. R. Dovey. *Analyst*, 1920, 45, 330—332.

AN apparatus for the determination of sulphur in steel, etc., consists of a small reaction flask provided with a side tube connected with a tube extending to the bottom of a test-tube; the latter contains an absorbent for the gas evolved from the flask. The test-tube is connected, in turn, with a U-tube containing a small quantity of the absorbent solution. A second apparatus described is suitable for the absorption of carbon dioxide in the wet combustion method for the determination of carbon in steel. The reaction flask is attached to a short reflux condenser through the centre tube of which the stem of a tapped funnel extends nearly to the bottom of the flask; the evolved gases are conducted through a tube leading from the top of the condenser to the jet of a burette containing

a rod fitted with discs and partially filled with barium hydroxide solution. The top of the burette is connected with an aspirator so that a current of air free from carbon dioxide may be drawn through the apparatus. At the end of the operation the burette is disconnected, and the jet passed through a rubber stopper closing a filter-tube, so that the barium carbonate formed may be filtered off without contact with the atmosphere.—W. P. S.

Weak acids; Titration of — with weak bases. I. M. Kolthoff. *Pharm. Weekblad*, 1920, 57, 787—796.

THE exact titration of a weak acid with a weak base is possible if the indicator is suitably chosen. An expression for the hydrogen-ion concentration of a solution of a salt of a weak acid and a weak base is derived, involving only the dissociation constants of the base, the acid, and water. With the help of this equation the degree of hydrolysis of the neutral salt solution may be calculated. An indicator is then chosen for which the colour change takes place at or about the same p_H . Exact results were obtained in the titration of ammonia with acetic, oxalic, succinic, formic, and salicylic acids, using in the first three cases neutral red as indicator, and methyl red in the last two.

—W. S. M.

Gases; Application of the thermal conductivity method to the automatic analysis of complex mixtures of —. E. R. Weaver and P. E. Palmer. *J. Ind. Eng. Chem.*, 1920, 12, 894—899.

THE method previously described (J., 1920, 470 A) is applicable in numerous directions. By comparison with a standard gas of known composition (air or hydrogen) helium may be determined in admixture with nitrogen, hydrogen in air, and impurities in hydrogen for balloons. Comparison of the thermal conductivity before and after a chemical reaction affords a means of determining chlorine, sulphur dioxide, acetylene, water vapour, etc., in various gaseous mixtures. Further, a gas, such as hydrogen, may be added to a mixture (flue gas), the oxygen removed by combustion, and its amount determined from the difference in the conductivity before and after the reaction. In other cases successive combustion with oxygen and hydrogen may be used, as in the determination of carbon monoxide in presence of large amounts of hydrogen.

—C. A. M.

Potassium and sodium; Estimation of — when present together [as chlorides]. A. Quartaroli. *Gaz. Chim. Ital.*, 1920, 50, ii., 64—69.

THE method consists in converting the mixture of chlorides into nitrates and determining the solidifying point of the mixed nitrates.—T. H. P.

Calcium and magnesium in different saline solutions; Estimation of —. E. Canals. *Comptes rend.*, 1920, 171, 516—518.

THE whole of the calcium and magnesium may be separated from the iron and aluminium in a solution containing salts of the four metals, by acidifying the solution with sulphuric acid, adding sodium phosphate, making alkaline with ammonia, and then acidifying with acetic acid and shaking vigorously for several minutes. In this way the calcium and magnesium pass into solution, whilst the precipitated iron and aluminium remain undissolved.—W. G.

Diphenyl derivatives; Use of — in qualitative analysis. F. Feigl. *Chem.-Zeit.*, 1920, 44, 689—690.

TO detect minute traces of manganese, ceric, cobaltic, or thallic compounds, their solution is rendered alkaline with sodium hydroxide, filtered, and the filter then treated with a drop of benzidine

acetate solution; an intense blue coloration is obtained. The reaction will detect 1 part of manganese in 125 million parts of solution. Thallic salt solutions give the coloration without previous treatment with alkali; slightly acid iron solutions and those from which the iron has not been precipitated completely by alkali also give a blue coloration with the reagent. Halogen- and alkyl-substituted benzidines and tolidines may be used in place of benzidine.—W. P. S.

Iodine; Estimation of —. E. C. Kendall. J. Biol. Chem., 1920, 43, 149—159.

MODIFICATIONS of the method previously published (J., 1912, 748) are described which enable the determination of iodine in blood and tissues to be carried out satisfactorily.—J. C. D.

Iodine; Estimation of — in blood and animal tissues. E. C. Kendall and F. S. Richardson. J. Biol. Chem., 1920, 43, 161—170.

A METHOD for destroying the large amount of organic matter in blood and animal tissues without loss of iodine is described. (Cf. J.C.S., n., 631.) —J. C. D.

Phosphoric acid; Estimation of —. Parts 1, to F. H. Kleinmann and J. Feigl. Biochem.-Zeits., 1919, 99, 19—190.

Estimation as magnesium ammonium phosphate and effect of serum constituents on the precipitation.—Serum constituents, e.g., dihydrogen potassium phosphate, urea, glycine, and calcium carbonate do not influence the precipitation of phosphoric acid as magnesium-ammonium-phosphate. The presence of sodium chloride in certain concentrations, however, leads to high results. Reagents employed in the precipitation of proteins, e.g., picric acid and trichloroacetic acid, influence the precipitation, although they do not hinder it. Serum does not contain any substances which are capable of preventing the complete precipitation of phosphoric acid as magnesium-ammonium phosphate. On precipitating 1 mg. P_2O_5 as magnesium-ammonium phosphate in a volume of solution of 50—75 c.c., 0.006 mg. remains unprecipitated. With a smaller quantity, e.g., 0.1 mg. P_2O_5 , the unprecipitated fraction is even proportionately higher.

Estimation as phosphoric acid-molybdenum complex phosphate.—The uranium acetate method yielded good results with quantities as low as 10 mg. P_2O_5 . Quantities below 10 mg. gave unreliable results. With Liebermann's silver phosphate method high results were obtained, while the estimation of phosphoric acid as the vanadium-phosphoric acid-molybdenum complex was found satisfactory.

Estimation as phosphoric acid-molybdenum complex. Gravimetric and colorimetric methods.—The precipitation of molybdenum by Raper's method gave too high values. The most suitable results were obtained with potassium ferrocyanide. 1 mg. of Mo was estimated in 100 c.c. with an error of 0.5%. The procedure was therefore successfully applied for the colorimetric estimation of phosphoric acid. 0.1 mg. of P_2O_5 can be estimated by this method with a 0.5% error. *Estimation in the phosphoric acid-molybdenum complex. Volumetric and sedimentic methods.*—Low results were obtained with Neumann's method for the estimation of phosphorus when the theoretical factor was used. By washing the phosphorus-ammonium-molybdate precipitate with 50% alcohol instead of with water better results were obtained. In micro-Neumann estimations it is more satisfactory to wash the precipitate than centrifuge it, as a certain amount of loss is thus obviated. A "sedimentic" method is described by means of which the phosphorus is rapidly estimated by measuring the volume of the precipitate after centrifuging it in a graduated tube. The height of

the phosphorus-ammonium-molybdate precipitate is proportional to its P_2O_5 -content. *Estimation as a strychnine-phosphoric acid molybdenum compound. (Nephelometry.)*—The development of nephelometry and a new nephelometer and its manipulation are described. *Estimation as a strychnine-phosphoric acid molybdenum compound. Special phosphoric acid nephelometry and a new preparation of the strychnine-molybdenum-reagent.*—Strychnine and molybdenum form a compound suitable for use in estimation of phosphoric acid. 0.1—0.0005 mg. P_2O_5 can be estimated in this way nephelometrically with an error of 0.5%.—S. S. Z.

Phosphoric acid; Volumetric determination of — by Neumann's method. P. Iversen. Biochem. Zeits., 1920, 104, 15—21.

THIS method for determining phosphorus in organic substrata consists in destroying the organic matter by treatment with sulphuric and nitric acids, precipitating the phosphate thus formed as ammonium phosphomolybdate, and washing the precipitate with ice-cold water, which is passed through a filter. The latter, together with all the precipitate, is then treated with rather more $N/2$ sodium hydroxide solution than is necessary to dissolve the precipitate, the ammonia thus liberated being boiled off and determined by titration: (e.c. of $N/2 NaOH$) $\times 0.5539$ = amount of phosphorus in mg. Gregersen found it to be necessary to over-titrate with 0.5—1 c.c. of acid and to boil to expel carbon dioxide. The author's results show that this modification gives good results provided that the excess of $N/2$ alkali taken is at most 4 c.c., and is subject to no systematic error; the mean value of the factor is found, from 25 analyses, to be 0.5526.—T. H. P.

Selenium [in organic compounds]; Estimation of —. F. Wrede. Z. physiol. Chem., 1920, 109, 272—275.

THE substance is burned in a tube in oxygen in presence of platinum as catalyst and the selenious acid formed is titrated with $N/100$ sodium hydroxide solution, sodium hydrogen selenite being neutral to methyl orange. When both sulphur and selenium are present, the mixed sulphuric and selenious acids obtained are titrated and the sulphuric acid then estimated separately as barium sulphate. If the substance contains either nitrogen or a halogen titration is useless, and the selenious acid may then be reduced by means of sodium sulphite in presence of a large amount of hydrochloric acid and the selenium thus formed weighed. The combustion is carried out in a so-called bead-tube (Pregl, "Die quant. org. Mikroanal.," 1917, 107) of about 7 mm. bore, the beads, previously moistened with water, serving for catching the selenious acid. In the empty part of the tube are placed one or two 5 cm. "stars" of thin platinum foil, the boat containing the substance lying between the "stars" and the end of the tube. The flow of oxygen should be 8—10 c.c. per min. Over the capillary end of the tube an Erlenmeyer flask is inverted, and into this the selenious acid is subsequently washed. Before being used for the first time the combustion tube is treated with caustic alkali solution and then with acid and is finally rinsed out thoroughly with freshly boiled distilled water to which methyl orange and dilute acid or alkali have been added until it is just not pure yellow; the excess of water is blown out, but the tube is not dried. The ignited platinum stars and the boat are introduced, the tube at the stars being heated to bright redness and the substance burnt very slowly. The selenious acid separates in shining white crystals at the beginning of the beads, the appearance of red selenium or of carbon indicating too rapid combustion. The acid is rinsed out into the Erlenmeyer flask by means of the methyl orange water and the solution titrated

with $N/100$ sodium hydroxide solution. If sulphur as well as selenium is present, the bead tube is moistened, before combustion, with neutral 5% hydrogen peroxide solution, the combustion being carried out as usual. The platinum stars are ignited after each combustion or etched with *aqua regia*, as they often become coated with a thin layer which reduces their catalytic action. The method gives good results with small quantities (0.02—0.06 g.) of substance.—T. H. P.

PATENTS.

Gas analysing and recording apparatus. A. B. Cunningham, Toledo, Ohio. U.S. Pat. 1,311,952, 5.8.19. Appl., 8.4.19.

THE gas is drawn into the apparatus by means of a water jet, and a measured volume is forced by the rising of the water level into an absorption tank wherein the soluble portion is absorbed; the residual gas passes to a measuring bell, where its volume is recorded. Arrangements are provided for automatically setting the apparatus after each test for a fresh operation.

Moisture in solid materials; Method and apparatus for determination of —. L. E. McAllister. U.S.P. 1,347,106, 20.7.20. Appl., 8.5.19.

THE apparatus comprises means for drying air, for determining the temperature of the dry air, for passing the air through a tube containing the sample, and for determining the change in temperature of the sample and the rate of flow of the air.—J. H. L.

Gases; Apparatus for automatic and continuous analysis and recording of —. W. D. R. Brown and W. T. Pickston. E.P. 149,752, 16.5 and 30.10.19.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Abbott. Non-conducting linings or coverings of heat retaining or excluding chambers. 28,621. Oct. 9.

Arcari. Combined mixing and crushing device. 28,255. Oct. 6.

Barbet et Fils et Cie. Distilling and rectifying columns. 27,689. Sep. 29. (Fr., 1.10.19.)

Baxter Asphalt Paving Co. 27,425. See IX.

Bedford, Fuller, and Roberts. Furnaces. 28,582. Oct. 8.

Bruhl. Grinding rollers or balls. 28,340. Oct. 6.
Douglas. Condensers, dephlegmators, and column stills. 27,965. Oct. 2.

Fraymouth, Reavell, and Kestner Evaporator and Engineering Co. Extraction of soluble matter from powdered material other than tanstuffs. 28,173. Oct. 5.

Keene. Filtering apparatus. 28,100. Oct. 4.

Kirkbride. Crushing mills. 27,816-7. Oct. 1.

Morison. Treatment of boiler feed etc. water. 28,590. Oct. 8.

Schmieding. Regenerative furnaces. 27,898. Oct. 1. (Ger., 30.6.19.)

Wade (Barrett Co.). 28,472. See XX.

COMPLETE SPECIFICATIONS ACCEPTED.

13,050 (1919). Bulgin, Hall, and Searle. Rotary machines for treating air or gases with liquids and *vice versa*. (151,314.) Oct. 6.

15,841 and 15,844 (1919). Smallwood. Furnaces. (151,366-7.) Oct. 6.

16,063 (1919). West and Hodgson. Kilns. (151,709.) Oct. 13.

16,247 (1919). Dressler Tunnel Ovens, Ltd., and Williamson. Continuous and intermittent ovens. (151,722.) Oct. 13.

16,665 (1919). Gilmour. Manufacture of heat-insulating material for steam and other pipes, boilers, etc. (151,738.) Oct. 13.

20,148 (1919). Davis. Pulverisers. (151,440.) Oct. 6.

25,673 (1919). Fleury and Robertson. Chambers for drying. (151,488.) Oct. 6.

29,687 (1919). Phillips and Rose. Comminution and mixing of materials. (151,508.) Oct. 6.

32,851 (1919). Imray (Kuntz). Rotary driers. (151,518.) Oct. 6.

10,565 (1920). Thaberg. Apparatus for extracting liquid from fresh peat and similar watery masses. (151,907.) Oct. 13.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Anderson and Macnochie. Gas-producer. 27,385. Sep. 27.

Burnell and Dawe. Motor spirit. 27,395. Sep. 27.
Chown. Carbonising, distilling, and briquetting carbonaceous material. 28,676. Oct. 9.

Goskar. Drying coal etc. 27,881. Oct. 1.

Goss (Blake). Manufacture of fuel for heat, light, and power. 27,811. Sep. 30.

Johnston. Liquid fuels. 27,771. Sep. 30.

Lewis. Distilling and gasifying solid carbonaceous materials. 27,910. Oct. 1.

Maxted and Thompson. Absorption of ethylenic hydrocarbons. 27,621. Sep. 29.

Morgan, and Thermal Industrial and Chemical Research Co. Manufacture of coal gas. 28,344. Oct. 6.

Neill and Russell. Gas-producers. 28,054. Oct. 4.

Rudder. Utilising waste products as fuel in steam-raising plant. 28,633. Oct. 9.

Sauer. 28,682. See XVII.

Tulloch. Fuel. 27,770. Sep. 30.

Wallace. Distillation of carbonaceous material. 27,798-9. Sep. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

15,295 (1919). Franklin. Suction gas generators. (151,329.) Oct. 6.

20,501 (1919). Wells. Gas-cleaning apparatus. (151,443.) Oct. 6.

20,568 (1919). Yeo. Gas-producers. (151,445.) Oct. 6.

22,544 (1919). Marbais and Deguide. Complete extraction of naphthalene from coal gas. (151,463.) Oct. 6.

1263 (1920). Grocott. Gas-producer. (151,520.) Oct. 6.

5220 (1920). Kennedy. Retorts. (141,025.) Oct. 13.

10,565 (1920). Thaberg. See I.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Glover, West, and West's Gas Improvement Co. Separation of liquor from tar and oils. 27,999. Oct. 2.

Wade (Barrett Co.). 28,472-3. *See* XX.

COMPLETE SPECIFICATION ACCEPTED.

22,544 (1919). Marbais and Deguide. *See* 11.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Dawson. Manufacture of leuco-alizarin bordeaux and derivatives thereof. 28,376. Oct. 7.

Imray (Soc. Chem. Ind. in Basle). Manufacture of dyestuffs. 28,008. Oct. 2.

COMPLETE SPECIFICATIONS ACCEPTED.

7719 (1918). Clarke (Chem. Fabr. Worms). Colours soluble in fats and oils and process of preparing same. (151,657.) Oct. 13.

16,042 (1919). Perkin. Manufacture of anthranol. (151,707.) Oct. 13.

31,611 (1919). British Dyestuffs Corp., Turner, and Badier. Manufacture of diphenylamine derivatives. (151,868.) Oct. 13.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Bearder and Schwartz. Manufacture of cellulose acetates for producing artificial silk, films, celluloid, etc. 27,973. Oct. 2.

British Cellulose and Chemical Manuf. Co., and Richardson. Treatment of products made with cellulose derivatives. 27,531. Sep. 28.

Bustamante. Obtaining cellulose from vegetable matter. 27,904. Oct. 1.

Dreyfus. Manufacture of cellulose derivatives. 28,350. Oct. 6.

Foster (Mahy). Treating flax, hemp, etc. 27,777. Sep. 30.

Kawabe. Treating ramie, hemp, etc. 27,933. Oct. 1.

Radeliffe. Production of cellulose acetate and artificial silk therefrom. 28,413. Oct. 7.

Ringer. Manufacture of a hard substance from fibres. 27,443. Sep. 27. (Austria, 19.2.20.)

COMPLETE SPECIFICATION ACCEPTED.

16,816 (1919). Johnson and Phillips, and Tracey. Process for making paper, string, etc. (151,391.) Oct. 6.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Carpmael (Bayer u. Co.). Manufacture of mordants and process of dyeing basic dyestuffs on cotton. 27,466. Sep. 27.

Radeliffe. Dyeing artificial silk. 28,412. Oct. 7.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Blanc and Jourdan. Treatment of leucitic rocks to render the potash available. 28,295. Oct. 6. (Ital., 6.10.19.)

Collins. Purification of zinc chloride. 28,551. Oct. 8.

Kelly. Manufacture of acid sodium pyrophosphate. 27,660. Sep. 29.

Maclaure. Production of aluminium and zinc salts. 28,326. Oct. 6.

Norsk Hydro-Elektrisk Kvaestofaktieselskab. Catalyst for making ammonia. 27,491. Sep. 29. (Norway, 28.10.19.)

Oldbury Electro-Chemical Co. Manufacture of oxalates and oxalic acid. 28,356. Oct. 6. (U.S., 23.3.20.)

Pease. Extraction of ammonia from fluids and production of ammonia etc. compounds. 28,311. Oct. 6.

Soc. l'Azote Français. Recovering nitrous vapours in form of aqueous nitric acid. 28,347. Oct. 6. (Switz., 8.10.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

7869 (1919). General Chemical Co. Production of nitric acid. (124,759.) Oct. 13.

15,026 (1919). Thompson. *See* XVI.

15,406 (1919). Phillips and Rose. Manufacture of readily soluble alkali silicates. (151,339.) Oct. 6.

19,085 (1919). Chailaux. *See* XIII.

VIII.—GLASS; CERAMICS.

APPLICATION.

Duckham, and Woodall, Duckham, and Jones. Gas-fired pottery kilns. 28,248. Oct. 5.

COMPLETE SPECIFICATIONS ACCEPTED.

15,764 (1919). Marks (Universal Glass Co.). Glass bait. (151,361.) Oct. 6.

26,095 (1919). Johnson. Manufacture of china and earthenware. (151,835.) Oct. 13.

19,445 (1920). Schott u. Gen. Reduction in size of the bubbles in glass. (147,487.) Oct. 13.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Baxter Asphalt Paving Co. Bituminous lining for surfaces exposed to corrosive action. 27,425. Sep. 27. (U.S., 2.1.15.)

Ringer. Working and increasing stability of objects made of Sorel cement. 27,444. Sep. 27. (Austria, 19.2.20.)

Uzzell. Concrete for building. 27,595. Sep. 29.

Wade (Pfaff). Hydraulic cement. 27,768. Sep. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

5208 (1919). Vecchis. Preserving and fire-proofing wood. (151,661.) Oct. 13.

16,665 (1919). Gilmour. *See* I.

20,174 (1919). Holzapfel and Walther. *See* X.

28,397 (1919). Honda. Road-making or paving material. (151,852.) Oct. 13.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Bourcoud. Reducing metallic oxides. 27,493. Sep. 27. (U.S., 17.1.18.)

Burden. Aluminium alloys. 28,087. Oct. 4.

Craven. Aluminium solder. 28,506. Oct. 8.

Selas-Turner Co., and Turner. Crucible furnaces. 28,049. Oct. 4.

Vivian. Treatment of ores etc. 28,436. Oct. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

15,174 (1919). August. Furnaces for heat treatment of iron, steel, etc. (151,323.) Oct. 6.

15,783 and 31,797 (1919). Elmore. Treatment of argenteiferous sulphide ores. (151,698.) Oct. 13.

15,916 (1919). Clegg. Treating tin scruff. (151,374.) Oct. 6.

- 16,401 (1919). Wild. Testing the hardness of ferrous metals. (151,383.) Oct. 6.
 17,320 (1919). Backer. Alloys. (151,400.) Oct. 6.
 20,174 (1919). Holzapfel and Walther. Composition for coating iron, steel, and wood. (151,793.) Oct. 13.
 21,603 (1919). Palmer, Seale, and Nevett. Flotation separation of mineral substances. (132,260.) Oct. 13.
 28,749 (1919). Wade (Lindsay Light Co.). Manufacture of thorium. (151,854.) Oct. 13.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

- Adam and Antonoff. Electrolysis. 27,573. Sep. 28.
 Heraeus Ges., Rohn, and Stahlwerke Lindenburg. Induction furnaces. 27,932. Oct. 1. (Ger., 19.5.20.)
 Lofts. Alloy for electric heating appliances. 27,510. Sep. 28.
 Meagher. Alloy for electrical make-and-break contacts. 27,964. Oct. 2.
 Thompson (Plauson). Electrodes. 27,727. Sep. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

- 14,559 (1919). Houston. Electric batteries. (151,680.) Oct. 13.
 32,793 (1919). Levin. Electrodes of electrolytic gas generators. (151,873.) Oct. 13.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

- Ashby. Manufacture and use of washing compounds. 28,482. Oct. 8.
 Peetz. Treatment of oils. 28,449. Oct. 7.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

- Clarke, and Cookson and Co. Manufacture of paints and enamels. 28,661. Oct. 9.
 Fitzgerald. Lithographic inks. 28,124. Oct. 4.

COMPLETE SPECIFICATIONS ACCEPTED.

- 8290 (1919). Ivinston and Roberts. Paint etc. (151,666.) Oct. 13.
 14,008 (1919). Simonson and Blair. Producing indurated compounds from lac or its derivatives. (127,825.) Oct. 13.
 14,845 (1919). Koppers Co. Manufacture of paint or varnish. (129,264.) Oct. 6.
 15,373 (1919). Schneider. Manufacture of paints. (151,687.) Oct. 13.
 15,860 (1919). Koppers Co. Manufacture of resin. (132,229.) Oct. 13.
 19,085 (1919). Chaillaux. Manufacture of gold-coloured sulphurs and vermilion of antimony. (151,422.) Oct. 6.
 28,726 (1919). Richard and Dubois. Paint. (151,853.) Oct. 13.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

COMPLETE SPECIFICATION ACCEPTED.

- 15,530 (1919). Davidson. Treatment of raw rubber when freshly coagulated from latex. (151,344.) Oct. 6.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

- Carmichael and Ockleston. Treatment of hides, skins, etc. 27,837-8. Oct. 1.
 Clark (Chem. Fabr. Worms). Tanning hides. 28,247. Oct. 5.
 Fraymouth, Reavell, and Kestner Evaporator and Engineering Co. Extraction of tannin from tanstuffs. 28,174. Oct. 5.

- Fraymouth, Reavell, and Kestner Evaporator and Engineering Co. Treatment of powdered etc. tanstuffs. 28,175. Oct. 5.

COMPLETE SPECIFICATION ACCEPTED.

- 16,672 (1919). Boston and Sons, and Fairrie. Liming of hides. (151,387.) Oct. 6.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

- Bitterling, Lyman, and Bitterlings, Ltd. Fertilisers. 28,158. Oct. 5.

- Dumont. Manufacture of combined phospho-organic manure. 28,001. Oct. 2.

- Soc. l'Azote Français. Granulating and coating calcium cyanamide. 28,059. Oct. 4. (Fr., 4.10.19.)

COMPLETE SPECIFICATION ACCEPTED.

- 15,026 (1919). Thompson (Comp. des Phosphates de Constantine). Mechanical treatment of tricalcic phosphates. (151,684.) Oct. 13.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

- Sauer. Manufacture of decolorising carbon. 28,682. Oct. 9.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

- Bedford, and Burmah Oil Co. Manufacture of alcohol. 28,352. Oct. 6.

- Holzverkohlungs Ind. A.-G. Production of vinegar. 28,227. Oct. 5. (Ger., 23.10.19.)

- Scott. Producing condition and head of draught beer. 27,738. Sep. 30.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

- Atmosterol, Ltd., and Wallace. Sterilisation, disinfection, etc. 28,102. Oct. 4.

- Carmichael and Co., and Guillaume. Treatment of offal, sewage, etc., and extraction of by-products. 28,258. Oct. 6.

- Coopman. Food product. 28,289. Oct. 6.

- Leffler. Manufacture of cocoa substitute. 28,126. Oct. 4.

- Leffler. Bettering smell and taste of foodstuffs. 28,127. Oct. 4.

- MacLachlan. Treatment of waste organic substances. 27,780. Sep. 30.

- Morison. 28,590. See I.

- Remington. Treatment of wheat. 28,235. Oct. 5.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

- Bedford, and Burmah Oil Co. 28,352. See XVIII.

- Blagden, and Howards and Sons. Manufacture of calcium, magnesium, and lithium acetylsalicylates. 28,343. Oct. 6.

- Dreyfus. Manufacture of alkyl compounds. 27,646. Sep. 29.

- Johnson (Badische Anilin u. Soda Fabr.). Manufacture of alcohols, ketones, etc. 28,657. Oct. 9.

- Wade (Barrett Co.). Purifying chemical compounds. 28,472. Oct. 7.

- Wade (Barrett Co.). Manufacture of oxidation products of naphthalene. 28,473. Oct. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

- 15,776-7 (1919). U.S. Industrial Alcohol Co. Apparatus for making esters. (130,969 and 130,970.) Oct. 6.

I.—GENERAL; PLANT; MACHINERY.

Evaporator design; Studies in —, W. L. Badger and E. M. Baker. Amer. Inst. Chem. Eng., 29.6.20. Chem. and Met. Eng., 1920, 23, 569-574. (See this J., 1920, 617A, 681A.)

THE influence of the elevation of boiling point, resulting from increase in salt concentration, upon the effective temperature drop between the heating steam and the liquid being evaporated is dealt with. If the boiling point rises and the temperature of the heating medium remains constant there results a loss of evaporator capacity but not of thermal efficiency. The published figures relating to increase of boiling point with increase of salt (NaCl) concentration differ considerably, and fresh determinations have been made. The results are given in a number of curves and tables, together with a

Evaporating liquors; Method of — and apparatus therefor. Metallbank und Metallurgische Ges. A.-G. E.P. 110,059, 9.2.20. Conv., 13.3.19.

Is an evaporator where the vapour from the liquor is compressed and used as the heating medium, the vapour which remains uncondensed after such use is returned to the liquor space of the evaporator or to some other point on the inlet side of the compressor, the object being to keep in circulation a larger quantity of vapour than is theoretically necessary, so that the partial pressure of any entrained air is reduced.—B. M. V.

Evaporation of liquids or recovery of vapours or gases developed therefrom; Apparatus for —. F. Merz. E.P. 150,785, 4.6.19.

A gas is kept in circulation between a cooling coil, a heating coil (or other means of cooling and heat-

bibliography of the subject. The more important results, taken from smoothed curves, are summarised in the above table.—W. H. C.

PATENTS.

Centrifugal pumps for acids and corrosive liquids. W. P. Thompson. From Union Espagnole de Fabriques d'Engrais, de Prod. Chim., et de Superphosphates. E.P. 127,831, 6.6.19.

To minimise vibration the shaft of the pump is supported at both ends on bearings well outside the pump, and the glands have double packings with means for forcing a lubricant to the space between the two rings of packing. The liquid to be pumped is admitted to both sides of the rotor, and a valve is provided on the inlet pipe which can be adjusted to produce a slight vacuum round the shaft in order to prevent the liquid from penetrating the packing.—B. M. V.

Mixing of gases with liquids or solids (e.g., hydro-generation of oils); Apparatus for intensifying the mutual action one on the other during —. La Soc. Anon. l'Oxyhydrique Française. E.P. 129,978, 11.7.19. Conv., 19.7.18.

AN apparatus, e.g., for use in the catalytic hydro-generation of oils, consists of a horizontal cylindrical vessel provided with a rotating eccentrically disposed agitator, the periphery of the blades of which is almost in contact with the lowest point of the vessel. When a finely-divided catalyst is present, the ends of the blades are scoop-shaped to scrape up the paste which settles at the bottom of the vessel, and project it into the gas above the liquid.—L. A. C.

ing), and a vessel containing the liquid to be evaporated. The vapour absorbed by the warm gas is condensed on cooling, and means are provided for heat interchange between the hot moist gas and the cooled dry gas. The surface of the liquid exposed to the gas is increased by such means as rotating discs, or nests of sheets intermittently dipped into the liquid, or fixed sheets in separate liquor compartments which are alternately filled and emptied.—B. M. V.

Electrical precipitation of particles from gases. D. K. Morris and F. H. Haviland. E.P. 148,659, 15.5.19.

THE gas or fume passages are of such a form that the fume is caused to flow rapidly around an edge or edges at which there is a strong electric field. The momentum of the heavier dust or particles causes them to pass beyond the edges, into a region where the field is weaker, whence they descend by gravity.—B. N.

Electrical deposition of particles from gases. L. Lodge, Assr. to The Lodge Fume Co., Ltd. U.S.P. 1,345,790, 6.7.20. Appl., 10.5.20.

CHAMBERS for use in the electrical deposition of particles from gases, are provided with plates forming channels for the gases, discharge electrodes situated transversely and longitudinally between the plates, and deflectors for deflecting the gases toward the sides of the channels when passing longitudinally by the discharge electrodes.—B. N.

Tunnel oven or kilns. C. Whitfield. E.P. 150,482, 2.7.19.

A SEPARATE burner or combustion chamber is provided to which air under pressure and gas are admitted through separate jets and ports, so that a short intense flame is produced which afterwards passes to the heating chamber proper. The jet of pressure air may also induce a current of hot air from the interior of the oven to the burner chamber.—B. M. V.

Furnaces or kilns. R. J. Anderson. E.P. 150,762, 4.4.19.

A VERTICAL furnace for the smelting of ores or conversion of chemical compounds is surrounded at the bottom by combustion chambers into which fuel and air are injected in numerous fine streams which intersect at a large number of points. The fuel is completely burnt and the products pass under pressure into the charge in the furnace. Additional combustion chambers are mounted on the main combustion chambers, and in these fuel is burned to carbon monoxide, which is also injected into the charge to act as a reducing agent.—W. F. F.

Furnace walls. E. Bernitz. E.P. 151,031, 12.3.19. Addn. to 119,599.

FURNACE walls provided with air ducts as described in the original patent (J., 1918, 723 A) are constructed of special bricks, formed with their corners cut off, or with circular depressions in their ends or sides or with holes formed through them.—B. M. V.

Furnace. J. G. Aarts. U.S.P. 1,352,338, 7.9.20. Appl., 11.8.16.

A SHAFT furnace is provided with hollow walls composed of highly refractory bricks provided with a large number of narrow heating flues with transverse baffles. The flues of the several bricks are in communication to form continuous flues from the bottom to the top of the furnace.—W. F. F.

Extracting water from any material containing it. F. Merz. E.P. 150,786, 4.6.19.

A CURRENT of air or other gas is circulated over the material to be dried or concentrated and over a hygroscopic material. The hygroscopic material is regenerated by passing over it dried air which may also be heated if desired.—B. M. V.

Drying processes. T. Boberg, and Techno-Chemical Laboratories, Ltd. E.P. 150,807, 6.6.19.

IN the method of drying described in E.P. 150,068 (J., 1920, 682 A) the material from the first stage of drying is conveyed along, or dropped down, a conduit in the presence of a moving heated gas.—B. M. V.

Dryer. C. Slattery. U.S.P. 1,354,223, 28.9.20. Appl., 6.11.19.

A FRAME having vertical standards is provided with a series of supports one above the other on which trays may be supported. A conveyor is adapted to move up and down beside the supports and place the trays at any desired height.—W. F. F.

Dehydration; Process of —. A. W. Browne. U.S.P. 1,351,279, 28.9.20. Appl., 31.5.17.

THE material containing water is treated with a solution of a dehydrating agent in a non-aqueous solvent.—B. M. V.

Still. A. C. Jewell. E.P. 150,940, 3.2.20.

THE upper or main part of the still extends downwards and fits closely into a detachable bottom to below the liquor level; the top rim of the bottom is bent outwards and at the same height a groove is formed round the main part of the still, so that

packing can be caulked in. By this arrangement the bottom may be rapidly detached and replaced by another adapted for a different method of heating.—B. M. V.

Subdivision and treatment of fluids for various purposes. E. L. Pease. E.P. 151,038, 14.4.19.

STREAMS of fluids issue through holes or jets in the walls of a number of parallel pipes, and are guided in thin, flat streams by bars or sheets of metal or refractory material preferably arranged as a sort of lattice work between the pipes. The process is applicable to mixing coal dust or the like or combustible gases with air, to washing or cooling gases, or to effecting heat interchange between gases and/or liquids.—B. M. V.

Rectifier and condenser. H. E. Beyer and W. G. Hall, Assrs. to Ingersoll-Rand Co. U.S.P. 1,352,648, 14.9.20. Appl., 25.1.19.

THE apparatus consists of a vacuum pan over which a rectifier is supported by means of a conical sheet, while a crown sheet placed above the opening of the vacuum pan acts as a baffle to intercept cooling liquid. The casing of the rectifier supports a condenser, through which cooling liquid is circulated and in which baffles are fixed so as to form chambers for collecting the distillate. Means are provided for returning the liquid in the rectifier to the vacuum pan and for draining the upper baffle chamber and the casing of the condenser.—A. R. P.

Condensing apparatus. J. C. Morton. U.S.P. 1,354,122, 28.9.20. Appl., 4.4.18. Renewed 23.8.20.

A TUBULAR condenser is made with concentric tubes, the inner being circular in cross section and the outer oval.—W. F. F.

Centrifugal machine and process of disintegrating [atomising] material. R. P. Perry, Assr. to The Barrett Co. U.S.P. 1,352,623, 14.9.20. Appl., 1.11.17.

MOLTEN material is introduced axially into the top of a closed, rotating vessel in the form of an inverted frustum of a cone. The side walls are perforated so that the molten material is projected along different horizontal planes, the velocity in each plane being higher than that in the plane below.—W. F. F.

Crushing machine. W. Ellk, Assr. to J. Sinkovitz. U.S.P. 1,352,797, 14.9.20. Appl., 26.3.19.

A CRUSHING machine comprises a pair of superposed annular surfaces which are rotated in opposite directions about their common vertical axis. The crushed material is discharged into a casing having a hood above it through which the material is exhausted. Any particles falling back from the hood pass through a central opening in the upper grinding member on to the central part of the lower grinding member, where they are crushed by grinding balls rolling on a circular track.—W. F. F.

Extraction; Process of —. T. J. Fairley, Assr. to Southern Pine Products Co., Inc. U.S.P. 1,353,035, 14.9.20. Appl., 14.7.17.

THE material to be extracted is placed in a closed vessel completely filled with water at 180° F. (82° C.), and the pressure in the vessel is increased by the injection of steam to about 50–70 lb. per sq. in.—W. F. F.

Cooling and crystallising hot solutions; Apparatus for —. Maschinenbau A.-G. Balcke. G.P. 321,773, 10.9.18. Addn. to 319,968 (J., 1920, 563 A).

THE lower part of each conveyor band in the apparatus described in the chief patent is parallel to the inclined bottom of the vessel, and the bands are provided with scrapers, which remove the crystals from the bottom and convey them away from the vessel.—L. A. C.

Evaporating, cooling, concentrating, washing, and other purposes; Method of and means for effecting intimate contact between liquids and gases for —. H. E. La Bour. E.P. 125,380, 3.1.19. Conv., 8.1.18.

SEE U.S.P. 1,318,774 of 1919; J., 1919, 937 A.

Drying of solid moist substances; Apparatus for —. A/S. Myrens Verksted. E.P. 110,173, 20.3.20. Conv., 7.2.18. Addn. to 105,072 (J., 1918, 280 A).

SEE U.S.P. 1,317,501 of 1920; J., 1920, 619 A.

Separating mixed gases; Process of and apparatus for —. F. E. Norton, Assr. to Jefferies-Norton Corp. U.S.P. 1,351,056 9, 28.9.20. Appl., 31.8.15, 20.10.15, 26.1.18, 28.1.18. Renewed 29.7.12, 29.7.19, 14.7.20, 14.7.20.

SEE E.P. 106,676-7 of 1916; J., 1917, 859.

Furnace-front. C. Zulver and L. E. Smith. U.S.P. 1,351,429, 28.9.20. Appl., 11.8.19.

SEE E.P. 132,977 of 1919; J., 1919, 853 A.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coals; Determination of sulphur forms in —. A. R. Powell. J. Ind. Eng. Chem., 1920, 12, 887—890.

THE method described by Powell and Parr (J., 1920, 145 A) is trustworthy for the determination of the different forms of sulphur in coal, but for rapid routine work the following modifications are suggested. Sulphates may be extracted by boiling the coal for a few mins. with hydrochloric acid (sp. gr. 1.12) and the pyrites then extracted by shaking for 2 hrs. with dilute nitric acid. The difference between the total sulphur and the sum of the sulphate and pyrites sulphur gives the amount of organic sulphur. Since dilute nitric acid dissolves small quantities of the unstable phenol-soluble form of organic sulphur, it is preferable to calculate the pyrites sulphur from the pyrites iron content. In the case of semi-bituminous coals and the harder varieties of bituminous coals, the sample must be digested for a long time with concentrated nitric acid before the residue from the extraction becomes completely soluble in ammonia. The sodium peroxide used for the determination of sulphur in coal should have a low and constant sulphur content.—W. P. S.

Coal and its products; Determination of the specific gravity of —. H. J. Hailstone. Gas J., 1920, 131, 566.

THE specific gravity of small coal, pitch, etc., can be determined by flotation, using a solution of sodium thiosulphate of sp. gr. 1.350. For materials (e.g., pitch) of sp. gr. 1.2—1.35, a small pellet of the substance is dropped into 10 c.c. of the solution, and water is then added from a burette until the pellet is just suspended in the liquid, neither floating nor sinking, and the volume of water added is noted. From a curve, the sp. gr. is obtained. For materials of less than 1.2 sp. gr. the thiosulphate solution is run into 10 c.c. of water until the pellet just begins to rise.—A. G.

Fuels; Valuation of — on the basis of their flame temperature. W. Schwier. Stahl u. Eisen, 1920, 40, 1033—1037, 1108—1111, 1170—1177, 1236—1240.

CALORIFIC value alone is not a safe criterion of the value of fuel for metallurgical purposes. In high temperature operations, only that portion of the heat which is given up when the products of com-

bustion are cooled to the working temperature of the furnace is effectively used. Therefore the flame temperature is of equal importance. The calorific value is no criterion of flame temperature, and this is particularly shown in the case of gaseous fuels. Loss of heat by radiation increases with rise of temperature, but the possible efficiency of heating operations increases more rapidly. A safer criterion for the comparison of fuels, it is suggested, is a "figure of value" $H_{ut} \times 10^{-6}$, where H_u is the net calorific value and t the theoretical flame temperature. The method of calculating t is described, and data for specific heats and heat capacities are tabulated. The utilisation of the "figure of value" in the study of a number of metallurgical heating operations is illustrated. In a fuel gas, the usefulness of a component depends on the nature of the other components which accompany it; thus the utility of a given quantity of carbon monoxide differs in water gas and producer gas, a difference which is reflected by the $H_{ut} \times 10^{-6}$ figures. The relative efficiencies of the different modes of consuming 1 kg. of carbon can be compared by this criterion. In the comparison of fuel gases, it is necessary to take account of dust, water vapour, tar, and sensible heat. The tar has an $H_{ut} \times 10^{-6}$ figure greater than that of coal. Moisture, owing to high specific heat in addition to the latent heat, has a markedly depressing effect on flame temperature, and yet it usually does not appear in analyses.

—H. J. H.

Silica bricks in coke-oven construction. J. Enzenauer. Glückauf, 1920, 56, 785—793.

AN account is given of two batteries of ovens built, the one in 1915 of silica bricks (SiO_2 , 95%, CaO 2%) and the other one year later of ordinary coke-oven silicious bricks (SiO_2 , 80%, Al_2O_3 , 16%). The higher thermal conductivity of the silica brick was recorded in a shorter coking period, 21 hrs. as against 29 hrs., in the latter battery. In spite of initially unpromising texture and brittleness of the silica brick walls, they are now in the better condition of the two. The silicious bricks are more extensively corroded by salt and more worn by erosion. The walls of silica brick are less susceptible to fusion or deformation due to unskilled attention. The yield of by-products may possibly be adversely influenced in the silica brick construction, but this does not outweigh the advantages of increased output of good coke and of gas. The fact that higher temperatures may be maintained in flues of silica brick without damage to the walls may be a temptation to shorten the coking period at the expense of by-products, but the rise in heat consumption finally renders such practice uneconomical. Material and thermal balance sheets of the two batteries are given.

—H. J. H.

Coal; Swelling of — during coking. F. Korten. Stahl und Eisen, 1920, 40, 1105—1108.

THE tendency to swell during carbonisation possibly depends on the variation in temperature and mode of decomposition of the bituminous cementing material (cf. Fischer and Glud, J., 1920, 258 A). The author proposes a test for the swelling on coking:—100 g. of the coal is coked under standardised conditions in a cylindrical crucible of iron closed by a perforated piston. The latter supports a weighted lever fixed at one end so that the free end moves in accordance with the rise or fall of the piston. The free end is made to trace a magnified record of the movement of the piston, i.e., of the change of volume of the coal, upon a revolving drum covered with paper. The results agree with large-scale practice. A coal with 27% of volatile matter which showed a contraction of 4% was known to be easily coked and pushed from the oven. Another coal with 14% of volatile matter expanded nearly 6% during carbon-

isation and 3.5% at the end. In practice the coke from this coal was difficult to push from the ovens, and then only with damage to the walls.—H. J. H.

Oil-shale; Treatment of — and description of a specially high-grade shale. M. Dolch. Oesterr. Chem.-Zeit., 1920, 23, 122–125, 130–131.

AN Austrian shale of specially high quality is described. It has sp. gr. 0.8, is bright yellow in colour, and resembles earth saturated with natural petroleum. In laboratory trials it yielded 31.2% of shale oil on dry distillation, and 42.4% on distillation with superheated steam. This contrasts with 12–14% from Scottish shales or the torbanite of South Africa, 20% from Norfolk shale, and 35% reported from New South Wales. In the redistillation of the oil a loss of 18–19% occurred, due to decomposition with evolution of gas from 250° C. onwards. 2 g. of the crude oil heated slowly to 300° C. in an atmosphere of nitrogen yielded more than 3 c.c. of carbon dioxide. The improved quality and quantity of the distillate with the use of steam is explained by the prevention of local overheating and the partial decomposition described above. The crude oil yields no pitch, a result approached in the case of tar from certain Bohemian lignites. The nitrogen content of the shale varies from 0.5 to 2.0%. On dry distillation 100 kg. of shale yields 25 cub. m. of gas of 6260 cal. per cub. m. A quantity of light paraffins equal to 6% on the shale could be removed from the gas and still leave it with a calorific value of 4000 cal. per cub. m.

—C. I.

Hydrocarbons; Oxidation of — by oxygen. Oxidation of paraffin wax. C. Kelber. Ber., 1920, 53, 1567–1577.

THE residue obtained by the oxidation of paraffin wax (J., 1920, 220 A), amounting to 90–100% of the original substance, is a yellowish mass, iodine value, 1–2; saponification value, 250–300; acid value, about 200. When purified by washing with water and subsequently hydrolysed, it yields a highly complex mixture of fatty acids. The following have been definitely isolated: capric, myristic, palmitic, heptadecanoic, stearic, and arachidic acids, and an acid, $C_{16}H_{32}O_2$, which is isomeric with palmitic acid and possibly identical with Bergmann's isopalmitic acid. (Cf. J.C.S., Nov.)—H. W.

PATENTS.

Coal and other minerals; Apparatus for washing —. P. Habets and A. France. E.P. 138,905, 10.2.20. Conv., 12.8.13. Addn. to 22,655/12.

THE washing apparatus is of the type in which the coal or mineral is carried in a stream of water through a launder having a number of slots in its bottom through which streams of water are directed upwards, and through which the heavier material falls. The horizontal length of the slots may be modified by baffles moved horizontally by means of a screwed rod, and a vertical baffle may also be provided at the edge of the slot to intercept part of the heavier material and provide an artificial slope in the bottom of the launder. The upper part of each separating pocket, below the slot, may be trapezoidal, and the lower part rectangular in vertical cross-section.—W. F. F.

Coal; Treatment of — especially in the manufacture of fuel briquettes. C. H. Smith. E.P. 125,379, 3.4.19. Conv., 3.4.18.

COAL is supplied from a storage bin to a crusher, and thence to travelling trucks by which it is conveyed to carbonising retorts, preferably constructed as described in E.P. 123,739 (J., 1920, 650A). Bituminous coal containing 36% volatile matter and 55% fixed carbon is used, and is carbonised at 850°–1200° F. (455°–650° C.), leaving a spongy residue containing 5–15% of volatile matter, which

is conveyed to a cooler to which water is supplied. The material is then mixed with pitch, crushed, and treated with steam to convert it into a plastic mass. The mass is mixed with water if necessary, moulded into briquettes, and transferred to an inclined furnace heated by combustion flues in the walls, the hot gases afterwards passing downwards through a regenerator to pre-heat the air supply. The furnace is heated to 1400°–1850° F. (760°–1010° C.), and the briquettes are finally cooled by a spray of water.—W. F. F.

Briquette dryer. R. S. Plummer, Assr. to American Briquet Co. U.S.P. 1,352,377, 7.9.20. Appl., 11.9.19.

THE briquettes are carried by a travelling conveyor which divides the drying tunnel into upper and lower compartments. Air is forced into the lower compartment at one end by a fan, and discharged from the upper compartment at the other end. A series of intermediate fans draw air from points along the length of the upper compartment and deliver it to the lower compartment, and means are provided for heating the air prior to its introduction into the first of the series of fans.—W. F. F.

Fuel; Manufacture of a solid —. Elektrizitätswerk Lonza. E.P. 144,589, 9.3.20. Conv., 16.9.19.

METALDEHYDE compressed into a coherent mass, with or without the addition of colophony, chloroform, or the like as binding agent, is used as a fuel.

Peat mass; Treatment of — and production of turf or peat briquettes. E. P. T. R. Ulmann. E.P. 149,869, 6.11.19.

THE peat mass is thoroughly disintegrated and mixed with water to form a homogeneous peat-sludge, in a rotary or turbine pump, which also produces the pressure necessary to force the mass through a pipe line directly to the drying place, where it is spread out in a thin layer and allowed to dry, being afterwards cut up into briquettes. The pipe line is composed of detachable sections, which can be removed from the line as the discharge advances over one area and can be rejoined as another area is spread with the peat mass.—A. G.

Burning pulverulent or liquid fuel in furnaces; Method of and means for —. J. E. Muhlfield. E.P. 150,230, 24.2.19. (See also E.P. 112,155; J., 1918, 83A.)

A MIXTURE of fuel and air is introduced in one or more streams into a preliminary combustion chamber or chambers leading in a direct line to the main combustion chamber but located outside the furnace and constituting a zone of smaller capacity than the main combustion chamber.—A. G.

Fuel; Process of and apparatus for burning —. E. C. R. Marks. From Schutz Hawley Co. E.P. 150,395, 27.5.19.

FUEL, e.g., coarsely crushed or pulverised coal, mixed with air, is fed tangentially into one end of a cylindrical furnace having refractory walls, and passes in a helical path to the other end of the furnace. The stream of fuel then returns axially through the furnace within the annular current. Incombustible solid matter may be withdrawn during the helical movement of the fuel. The two ends of the annular space may be interconnected to equalise the pressures.—W. F. F.

Fuel; Apparatus for the combustion of —. R. J. Anderson. E.P. 150,761, 4.4.19.

FUEL, which may be solid, liquid, or gaseous, is projected tangentially into an annular combustion chamber surrounding a heating chamber, and the air for combustion is supplied to a number of perforated pipes of refractory material which project radially into the combustion chamber. The air is thus projected transversely across the fuel jet and

an effective mixing is obtained. The air nozzles may be arranged in rows in stepped formation.

—W. F. F.

Combustible material contained in the ashes from industrial furnaces and steam boilers; Process for the recovery of —. A. Andre. E.P. 151,192, 30.12.19.

THE ashes are fed into an inclined conduit having a gap in the lower wall midway of its length. A current of air is delivered by a blower horizontally through the gap into the conduit and separates the lighter combustible material from the heavier slag. The former passes into the lower part of the inclined conduit and the latter falls through the gap into a vertical discharge conduit.—W. F. F.

[Gas] *retorts or ovens; Introduction of steam into vertical* —. Woodall, Duckham, and Jones, Ltd., and A. McD. Duckham. E.P. 150,589, 18.12.19.

STEAM is superheated above 700° F. (370° C.) by passing it through tubes built in or about the waste gas flues of a vertical externally-heated retort, and then discharged through nozzles into the lower part of the retort.—W. F. F.

Coking coal. A. Roberts, Assr. to American Coke and Chemical Co. U.S.P. 1,352,696, 11.9.20. Appl., 1.12.19.

METALLURGICAL coke is obtained from coals in which the disposable hydrogen does not exceed 5% of the disposable oxygen, by heating the retort very rapidly when first charged. The temperature of decomposition of the resinous constituents is reached before excessive volatilisation has taken place and a sufficient resinous residue is left to bind the mass.—C. I.

Gas producers. A. L. Galusha. E.P. 129,971, 24.6.19. Conv., 15.7.18.

A PRODUCER is combined with a gas engine, and the steam requisite for the producer is generated by introducing water into the exhaust pipe of the engine, the pressure being regulated by an adjustable deflector extending partially across the exhaust pipe. The mixture of steam and combustion products is deflected into a dome, and forced by its own pressure into the steam-supply pipe of the producer. This extends into the larger air inlet pipe, and draws in air by injector action. Excess of water in the exhaust pipe may be used to keep the pipe free from salts, sludge, etc.—A. G.

Gas producers. G. H. Bentley and E. G. Appleby. E.P. 119,759, 16.5.19.

THE shell of the producer is mounted eccentrically and rotates around the grate, which is mounted upon a frame, together with a trough forming a water-seal. The frame is supported by columns, and the shell rotates upon rollers on the frame. The ashes are thereby discharged without the use of a tray and scrapers.—A. G.

Gas producers. H. M. N. Milton. E.P. 149,790, 26.5.19.

A CHAMBER, divided by a water-seal into compartments, is interposed between the producer proper and the gas holder. Each of the compartments receives gas primarily from a portion of the producer, and each can be separated from the general gas circulation. The grate of the producer is divided by a diaphragm dipping into a water-seal. A portion of the producer may thus be isolated for cleaning etc. without cutting off the gas supply.—A. G.

Producer gas; Generation and utilisation of —. A. H. Lynn and N. E. Rambush. E.P. 150,787, 4.6.19.

THE waste heat of a gas-fired furnace is employed

to raise steam for the producer blast by the use of vessels resembling gas washers (E.P. 11,452/12 and 741/13; J., 1912, 1167; 1913, 1117). In one such vessel a shower of water is heated by the hot burnt gas, and in another the heated water saturates and warms the air blast to the producer. Between these two vessels a third vessel may be interposed, in which the hot producer gas neutralises the acidity of the heated water and further heats it.—C. I.

Producer gas plants and internal combustion engines supplied therefrom. D. J. Smith. E.P. 151,087, 11.6.19.

IS a gas producer plant, combined with an internal combustion engine, the water for use in the producer is preheated by passing it successively through the engine jacket, through a tubular water heater heated by the engine exhaust gases, and through a heater heated by the producer gas on its way to the engine, and then passes into a boiler mounted on the producer. The waste heat of the plant is thereby fully utilised.—W. F. F.

Gas generator; Pulverised-fuel —. N. F. X. Beaugard. U.S.P. 1,351,460, 31.8.20. Appl., 21.5.17.

POWDERED fuel mixed with air is subjected to intense heat, then mixed with an additional supply of air and supplied to a furnace chamber for combustion. Air is supplied to the inlet end of a conduit, together with the powdered fuel, and a supplementary supply of air is added at the outlet end of the conduit, the intermediate part of which is heated.—A. G.

Carbon and gaseous fuel; (a) Process and apparatus and (b) process for producing —. J. R. Rose. U.S.P. (a) 1,352,085, and (b) 1,352,086, 7.9.20. Appl., (a) 8.11.18, (b) 26.12.18.

(a) AN "acriform hydrocarbon fluid" is introduced into a generator in which it is decomposed into solid carbon and a gas containing a preponderating amount of hydrogen, by the heat of an electric arc. (b) A mixture of hydrocarbon fluid with insufficient oxygen for its complete combustion is subjected to "discontinuous resistance material in an electric circuit," e.g., coarse material packed between electrodes, whereby carbon and a gas rich in hydrogen are produced.—J. H. L.

Gas; Method of generating —. H. Batchelor. U.S.P. 1,352,241, 7.9.20. Appl., 8.2.17. Renewed 13.1.20.

TWO separate masses of porous refractory material are alternately heated and sprayed with a homogeneous mixture of hydrocarbon and water. The gas generated is passed through a third mass of refractory material.—W. F. F.

Cyanogen [compounds]; Recovery of — from coal-gas. J. J. Hood. E.P. 141,398, 14.3.19.

AFTER removing hydrogen sulphide and carbonic acid from the gas in a lime purifier, the gas is treated, in the same purifier, with slaked lime impregnated with a solution of an iron salt, such as ferrous sulphate. Ferrous sulphate may be added, for example, to the lime in a tier of the purifier near the exit. The cyanogen compounds in the gas are fixed as calcium ferrocyanide, and by leaching or agitating the spent purifying material with dilute alkali, a solution of alkali ferrocyanide is obtained.

Fuel; Aeroplane motor —. U.S. Industrial Alcohol Co., Assces. of A. A. Backhaus. E.P. 128,917, 16.6.19. Conv., 25.6.18.

THE fuel is composed of 40 to 60% of alcohol (98%), 25% to 35% of benzol, and 30% to 50% of gasoline or naphtha.—A. G.

Hydrocarbon liquids; Production of — from carbonaceous material and apparatus therefor. F. P. A. Rousseau. E.P. 132,490, 4.6.19. Conv., 9.9.18.

CARBONACEOUS material such as coal, peat, bitumen, resins, pitch, oils, wood, or the like, in a finely divided condition, is distilled under pressure in an autoclave heated by external coils. The material is fed into the autoclave through a long shaft fitted with two valves between which the charge is isolated to prevent the entry of air, and, in the case of solid material, falls on to a hearth situated near the top of the autoclave. Several of the autoclaves are arranged around a common vessel in the form of an inverted cone heated at the top by a coil and connected with each autoclave by a slide-valve. The distillation products collect in this vessel and pass through a tube at the lower end into a condenser. In treating material with a relatively high carbon content, hydrogen may be admitted into the autoclaves.—L. A. C.

Petroleum; Process of cracking —. L. P. Lowe and F. C. Ruff, Assrs. to By-Products Manufacturing Co. U.S.P. 1,351,859, 7.9.20. Appl., 15.1.17.

A CRACKING chamber filled with openwork material is heated by means of products of combustion to a temperature above that at which petroleum is cracked to produce carbon and condensable hydrocarbons but below that at which petroleum is converted into permanent gas. Petroleum is then passed through the chamber, and subsequently, after stopping the supply of petroleum, the carbon deposited on the surface of the openwork material is burnt to assist in again attaining the requisite temperature to repeat the process.—L. A. C.

Electrochemical treatment of [hydrocarbon] vapours; Electrical apparatus for the —. L. B. Cherry. U.S.P. 1,345,431, 6.7.20. Appl., 9.10.17.

LIQUID hydrocarbons are vaporised in a still, and the vapours on their way to a condenser pass through a conduit consisting of a series of elongated, metallic, tubular units, united by cross connexions to form a continuous treating chamber. The wall of the chamber is maintained approximately at a red heat by means of solenoids, which are arranged longitudinally outside the units but insulated therefrom, the units being heated by induction. The solenoids are composed of a good electrical conductor, through which an alternating current is passed, and means are arranged for controlling the current to vary the temperature of the units. The vaporised products are simultaneously subjected, whilst passing through the heated chamber, to a high-frequency electric current discharge.—B. N.

Hydrocarbons; Apparatus for treatment of —. W. F. Rittman. U.S.P. (A) 1,352,916 and (B) 1,352,917, 11.9.20. Appl., (A) 3.8. and (B) 7.11.17.

(A) A TUBE passes upwards through the lower end of a vertical retort, and the portion within the retort is provided with openings for the passage of liquids. Hydrocarbons are passed into the lower end of the annular space between the tube and the retort, which is maintained at a suitable temperature for vaporising and cracking the hydrocarbons, and the products pass into the central tube, or the hydrocarbons are passed into the central tube and the products pass into the annular space. (B) Oil is fed into an auxiliary retort, so arranged that it receives heat from a main vertical retort arranged in a furnace. A constant quantity of the oil is maintained in the auxiliary retort, and the overflow passes into the main retort.—L. A. C.

Mineral oils; Process for treating —. W. Johnson. U.S.P. 1,354,257, 28.9.20. Appl., 25.4.16.

HEAVY mineral oil vapour is superheated and cracked by passage through an electric arc.

—L. A. C.

Paraffin; Process and apparatus for purifying crude — crystallising in scales, by sweating. E. Bartusch. G.P. 307,625, 29.8.17.

THE adhering oils, impurities, etc., are removed along the shortest possible horizontal path, through perforated surfaces which surround the material laterally, by increasing the pressure in a direction at right angles to that of the expressed oil and by raising the temperature at the same time.—J. H. L.

Hydrocarbon mixtures; Separation of solidified constituents, e.g., paraffin, from the sulphurous acid solution containing unsaturated hydrocarbons, in the treatment of — with liquid sulphur dioxide. Allg. Ges. für Chem. Ind. G.P. 322,754, 17.3.17.

AFTER the treatment of the hydrocarbon mixture with liquid sulphur dioxide the main portion of the sulphur dioxide extract, containing unsaturated hydrocarbons, is drawn off, and the residue, consisting of saturated hydrocarbons, with solidified hydrocarbons and some included residual extract, is heated in a special vessel until this residual extract has formed a distinct layer, whereupon it is separated and united with the main portion of extract.—J. H. L.

Subdivision and treatment of fluids. E.P. 151,038. See I.

Separating hydrogen sulphide from gases. G.P. 322,938. See VII.

Acetyl content of wood. Schwalbe and Becker. See V.

PATENT.

Glass surfaces [electric lamp bulbs]; Substances for coating —. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 150,598, 8.1.20.

THE glass surface is sand-blasted and coated with a mixture of, e.g., 5 pts. of hydrous magnesium silicate (French chalk), 5 pts. of zinc oxide, 15 pts. of sodium silicate (sp. gr. 1.375), and 8 pts. of water. When the coating is dry a thin layer of varnish is applied. The zinc oxide may be replaced by a coloured material, such as burnt sienna.—L. A. C.

III.—TAR AND TAR PRODUCTS.

Thionaphthene in coal tar. R. Weissgerber and O. Kruber. Ber., 1920, 53, 1551—1565.

CRUDE naphthalene is sulphonated with a greatly deficient amount of sulphuric acid at 90°—100° C., and the sulphonated product is decomposed by steam in the presence of a little sulphuric acid at 145° C.; the distillate has m.p. 73° C. and contains 2.3% S. Repetition of the process gives a material containing about 5—6% S, which can be increased to 12—14% by freezing out the naphthalene. The product obtained in this manner is dissolved in glacial acetic acid and treated with hydrogen peroxide when thio-

naphthene-S-dioxide, m.p. 142° C., is obtained, identical with the synthetic product, thus giving the first proof of the presence of thionaphthene in coal tar. Thionaphthene can be isolated from enriched naphthalene by Friedländer's mercuric acetate method, but it is essential to guard against undue rise in temperature during the formation of the additive compound; this can be easily accomplished by operating with methyl alcoholic solutions. By a similar process of partial sulphonation, followed by the use of mercuric acetate, thionaphthene has been isolated from technical "pure" naphthalene (containing 0.3–0.4 S), about 2 g. of the substance being obtained from 80 kg. naphthalene. For the industrial preparation of thionaphthene from crude naphthalene better results are obtained by the use of sodamide or preferably sodium and ammonia than with sodium; reaction is complete at 120° C.; practically the whole of the thionaphthene is regenerated when the sodium compound is treated with water; the process is applicable to "enriched" naphthalene. Sodium-thionaphthene appears to consist of about two-thirds of the monosodium and one-third of the disodium derivative. It is converted by carbon dioxide in the presence of an inert solvent into a mixture of thionaphthene-2-monocarboxylic and thionaphthene-2,3-dicarboxylic acids, which can be separated by taking advantage of their widely differing acidities or by fractional distillation of their esters. The dicarboxylic acid is readily transformed into the corresponding imide, m.p. 236° – 237° C., which when degraded by Hofmann's method yields exclusively 3-hydroxythionaphthene, thus affording a ready method of converting thionaphthene into Thioindigo Red. (Cf. J.C.S., Nov.)—H. W.

Diphenylene sulphide in coal tar. O. Kruber. Ber., 1920, 53, 1566–1567.

The presence of diphenylene sulphide in crude phenanthrene (containing about 1% S) has been established by oxidising the latter in hot glacial acetic acid with hydrogen peroxide, whereby diphenylene-sulphone, m.p. 229° – 230° C., is obtained.—H. W.

Aniline; Physical constants of — C. J. Knowles. J. Ind. Eng. Chem., 1920, 12, 881–883.

Pure aniline has the following physical characters:—Freezing p., -6.21° C.; b. p., 181.32° – 181.39° at 760 mm.; sp. gr. at $15^{\circ}/15^{\circ}$ C., 1.0268; $n_D^{20}=1.5850$. The freezing point appears to be the best criterion of the purity of aniline; the percentage (X) of aniline in a sample may be obtained from the formula $X=108.79+1.41t$, where t is the observed freezing point.—W. P. S.

Phenols; Conductometric titration of — I. M. Kolthoff. Z. anorg. Chem., 1920, 112, 187–195.

PHENOL and the cresols can be accurately titrated in $N/10$ — $N/100$ solution with alkali by the conductometric method. The hydroxy group in vanillin, sodium phenolsulphonic acid, salol, and methyl salicylate can be similarly titrated. Salicylic acid behaves as a monobasic acid, the hydroxy group having no acidic character, but *p*-hydroxybenzoic acid behaves as a dibasic acid. The hydroxy group in thymol and β -naphthol can also be titrated conductometrically. Catechol behaves as a monobasic acid, the second hydroxy group having no acidic properties, whilst resorcinol and quinol are dibasic. Resorcinol is best titrated with barium hydroxide; when sodium hydroxide is used the breaks in the conductivity curve are not distinct. Pyrogallol and phloroglucinol function as dibasic acids and gallic acid as a tribasic acid.—E. H. R.

Humic acids; Synthesis of — [from phenols]. W. Eller and K. Koch. Ber., 1920, 53, 1469–1476.

THE oxidation of phenols in alkaline solution leads to the formation of substances which have all the properties of natural humic acids. Thus solutions of catechol, quinol, or *p*-benzoquinone when exposed to air or treated with solid potassium persulphate give a product of the composition, $C_{11}H_6O_5$, whilst phenol gives a similar humic acid which is distinguished, however, by its greater solubility in alcohol. In general, only those phenols give humic acids which are capable of yielding quinonoid intermediate products. It would thus appear that there are a number of natural humic acids and that these substances when pure are free from nitrogen, and their acidic properties are probably due to the presence of an unchanged phenolic hydroxy-group. (Cf. J.C.S., Nov.)—H. W.

Sp. gr. of coal etc. Hailstone. See IIA.

PATENTS.

Benzene; Hydrogenation of — The Dayton Metal Products Co., Assocs. of T. Midgley, jun. E.P. 133,666, 7.5.19. Conv., 5.10.18.

A MIXTURE of benzene vapour and hydrogen is passed at a pressure of about 300 lb. per sq. in. over a catalyst, e.g., nickel oxide, maintained at about 300° C. By adjusting the rate of feeding the benzene into the apparatus, hydrogenation may be effected to yield either cyclohexane or a mixture of cyclohexane and benzene in any desired proportion, such as the eutectic mixture claimed in E.P. 133,667.—L. A. C.

Hydrogen for catalytic reactions. G.P. 301,361. See VII.

IV.—COLOURING MATTERS AND DYES.

Azo dyestuffs; Obtaining — by coupling diazo compounds with certain oxazine and chrome mordant dyes. E. Justin-Mueller. Rev. Gén. Mat. Col., 1920, 24, 130.

DIAZOTISED α -naphthylamine, ethoxybenzidine, or paranitraniline may be coupled with such oxazine dyes as Gallocyanine, Modern Violet, and phenocyanine and with azo chrome mordant dyes (diazotised benzidine sulphonatedisulphonate may also be used) to produce dyestuffs sparingly soluble in water but soluble in sodium bisulphite, and suitable for printing. A suitable printing paste is made by allowing 3 pts. of dyestuff with 2 pts. of sodium bisulphite of 38° B. (sp. gr. 1.36) to stand overnight, adding 2 pts. of glycerin and 24 pts. of gum solution, warming, cooling, and adding 6 pts. of chromium acetate of 20° B. (sp. gr. 1.16). The printed cloth is steamed for 1 hr., soaped at 80° C., and dried. The moss green to marine blue effects so obtained are fast to washing, soaping, air, and light.—A. J. H.

Yellow AB and Yellow OB in mixtures; Detection and determination of — W. E. Mathewson. J. Ind. Eng. Chem., 1920, 12, 883–887.

THE oil-soluble dyes Yellow AB (benzenazo- β -naphthylamine) and Yellow OB (*o*-toluenazo- β -naphthylamine) may be separated from Butter Yellow and Sudan I by means of petroleum spirit and sulphuric acid of different concentrations. When a solution of 0.011 g. of Yellow AB in 40 c.c. of petroleum spirit is shaken with 13N sulphuric acid and the acid extract shaken in turn with fresh portions of petroleum spirit, 92% of the dye will be found in the acid solution. Under similar conditions only 10% of Yellow OB can be recovered from

the acid solution. With 16N sulphuric acid 99% of Yellow OB passes into the acid solution, whilst all the Sudan I which may be present remains in the petroleum spirit. Butter Yellow is removed entirely from its solution in petroleum spirit by 10N sulphuric acid, but Yellow AB remains in the petroleum spirit layer. Spectrophotometric data are given which have been applied to the quantitative determination of the four dyes mentioned.

—W. P. S.

Thionaphthene. Weissgerber and Kruber. See III.

PATENT.

Dyestuffs; Manufacture of indigoid —. A. Jolles. G.P. 305,559, 17.10.15. Conv., 7.10.14. Addn. to 305,558 (J., 1919, 894A).

In the process described in the chief patent the aromatic hydroxy compound is replaced by 3-hydroxy-(1)-thionaphthene or its 2-carboxylic acid, or derivatives of these. An example is given of the preparation of 2-thionaphthene-2-indole-indigo from indoxyl acid and 3-hydroxy-(1)-thionaphthene.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cellulose; Preparation and properties of a highly-oxidised —. E. Knecht and L. Thompson. J. Soc. Dyers and Col., 1920, 36, 251—255.

PREVIOUS methods for preparing oxycellulose are open to criticism, since they take no account of its decomposition by alkalis into non-reducing substances and its hydrolysis by acids. An oxycellulose is obtained by treating filter paper with an acid solution of potassium permanganate (either 1 or 2 atoms of oxygen to 1 mol. of cellulose, $C_6H_{10}O_5$), washing the brown powder so formed, decolorising with hydrogen peroxide, and drying at a temperature not exceeding 40° C. This oxycellulose has strong reducing power, especially in the presence of alkalis, and readily reduces Methylene Blue, Safranin, Rosinduline, Indigo, and Indanthrene in the presence of caustic soda. Thus the formation of oxycellulose may account for the well-known bleeding of Indanthrene and vat colours during kier boiling. It reduces solutions of silver, cupric, and ferric salts. With ammonia and sodium bisulphite it forms unstable compounds. A strong yellow colour develops with caustic soda, and on neutralising the solution an acid cellulose is precipitated which has only slight reducing power. It is not possible to estimate oxycellulose by means of its reaction with *p*-nitrophenylhydrazine, since only adsorption compounds are formed. The new oxycellulose had a copper number of 14.2 as compared with 7.6 for Nastjokoff's bleaching powder oxycellulose. (Cf. J.C.S., Nov.)—A. J. H.

Cellulosic substances; Accelerated method of estimating the reducing values of —. E. Knecht and L. Thompson. J. Soc. Dyers and Col., 1920, 36, 255—257.

THE Schwalbe method for determining the copper number of oxycelluloses is modified by dissolving the precipitated cuprous oxide in a ferric salt solution and estimating the ferrous salt so produced with permanganate. A confirmatory value is obtained by estimating the unreduced copper in the filtrate with titanous chloride, and the difference between the two values is equal to the copper hydrate number (unreduced copper absorbed by all celluloses). The two methods give nearly identical results, which are slightly lower than that obtained by the original Schwalbe method. The possible effect which the alkalinity of Fehling's solution may have on oxy-

cellulose can be avoided by heating the oxycellulose with a solution of cupric thiocyanate containing sodium carbonate, treating the precipitate of cuprous thiocyanate with warm caustic soda, and estimating the cuprous oxide so formed with a solution of a ferric salt and potassium permanganate. The method is less liable to error, but the copper number so obtained is slightly high. The copper number was shown to be a reliable criterion of the reducing power of cellulose, by heating oxycellulose with caustic soda and Rosinduline and then titrating with titanous chloride.—A. J. H.

Cellulose in woods; Determination of —. S. A. Mahood. J. Ind. Eng. Chem., 1920, 12, 873—875.

SAMPLES composed of particles of a uniform size are essential if comparable results are to be obtained in the determination of cellulose in woods, and it is recommended that the material (sawdust) used for the determination should pass an 80-mesh sieve and be retained by a 100-mesh sieve. The most satisfactory material for analysis is obtained by sawing the wood and then grinding the sawdust. Sieber and Walter's modification of the chlorination process, in which the material is allowed to remain in the crucible throughout the treatment with chlorine and sodium sulphite (J., 1913, 974), gives a lower yield of cellulose than does the original method of Cross and Bevan, probably because of the higher temperature during chlorination. The modification proposed by Johnsen and Hovey, comprising preliminary hydrolysis with acetic acid in glycerin at 136°—140° C. (J., 1918, 132T) appears to be untrustworthy, since the cellulose is attacked as well as the hemicelluloses and furfural-yielding substances.—W. P. S.

Wood and lignin; Acetyl content of —. C. G. Schwalbe and E. Becker. Z. angew. Chem., 1920, 33, 225—226.

THE statements by Pringsheim and Magnus (cf. J., 1919, 714A; 1920, 263A) that the greater quantity of the acetic acid obtained from wood products is derived from the lignin are controverted. Probably only one-third of the acetic acid has its source in this substance.—W. P. S.

Lignin. III. Preparation of a tannic acid from lignosulphonic acids. M. Hönig and W. Fuchs. Monatsh. Chem., 1920, 41, 215—222. (Cf. J., 1920, 330A.)

THE barium salts of the three fractions of the lignosulphonic acids are converted by boiling aqueous barium hydroxide solution into different insoluble compounds, which have not been identified, and a single soluble salt, $C_{12}H_{10}O_{10}S_2Ba$, the acid corresponding to which has the character of a tannic acid of the catechu group with properties which are somewhat modified by the sulphur content; when fused with potassium hydroxide, it gives protocatechuic acid in good yield. (Cf. J.C.S., Nov.)—H. W.

PATENTS.

Retting flax; Process for —. L. A. Johnson. E. P. 151,143, 20.8.19.

WHITE and silky fibres are produced when flax, previous to retting, is steeped for successive periods in a solution containing 2% (on the weight of flax) of natural Magadi soda, which contains 43.55% of sodium carbonate and 40.41% of sodium bicarbonate, whereby gum and resin compounds unfavourable to the retting bacteria are removed. It is advantageous to add 0.5% (on the weight of flax) of Magadi soda to the retting liquors, which should be maintained at 80°—95° F. (25°—35° C.), and periodically aerated.—A. J. H.

Cellulose solutions; Production of artificial fibres from —. K. Schreiner. G. P. 322,538, 25.12.17.

The method of producing fine threads by drawing out thick threads spun from wide orifices, is applied to cuprammonium cellulose solutions with the aid of slowly acting gaseous precipitants. After use the gases are passed into a well-cooled tubular vessel in which the moisture is deposited and the greater part of the ammonia is absorbed; after being moistened and reheated the gases are used again to extract ammonia from the threads. —A. J. H.

Nitrocellulose film of low inflammability. J. G. Jarvis. U.S.P. 1,351,401, 28.9.20. Appl. 13.3.19

FILMS of low inflammability are made from a solution of nitrocellulose and acetylcellulose, to which are added an acetone-collodion and chloral hydrate together with cinchonine.—A. J. H.

Cellulose ethers; Process for increasing the softness and flexibility of articles made from —. Farbenfabr. vorm. F. Bayer und Co. G.P. 322,619, 20.3.17.

DIETHYL resorcinoldicarbonate, $C_6H_4(O.CO_2.C_2H_5)_2$, b.p. 298°—302° C., is used. Ethylcellulose can be worked with 50% of its weight of this substance without crystallisation occurring.—A. J. H.

Adhesive for joining articles made of cellulose derivatives to the same or other materials. Farbenfabr. vorm. F. Bayer und Co. G.P. 322,613, 21.1.17.

ESTERS or ethers of phenols or naphthols are employed for the purpose, e.g., β -naphthol anyl ether may be used as an adhesive for ethylcellulose.

—L. A. C.

Digesters and the like used in paper making and the like; Stationary —. S. Milne. E. P. 150,782, 4.6.19.

A VERTICAL cylindrical digester has a conical lower portion within which are perforated plates for supporting the grass or like material under treatment. A valve at the lowest part of the digester has a hollow spindle connected at the upper end with a perforated pipe passing into the lower part of the digester. During digestion the liquor drains through the perforated plates, passes out from the space between the plates and the outer walls, and is returned to the top of the apparatus by a steam injector or pump; when the process is complete the valve at the bottom is opened and the contents are washed out by water, spent liquor, steam, or air, and forced under pressure into the digester through the valve spindle and perforated pipe.—L. A. C.

Cellulose waste liquor; Manufacture of a material resembling dextrin from —. M. Clauss. G.P. 322,688, 15.2.18.

CELLULOSE waste liquor is improved both in adhesive properties and in colour by treatment below 100° C. with acids, sulphates, and a sulphonylate. —L. A. C.

Waterproof paper or felted sheets; Manufacture of —. L. Kirschbraun. E.P. 151,029, 6.3.19.

Paper-stock; Separating wax-like material from —. W. H. Smith. U.S.P. 1,352,553, 14.9.20. Appl. 21.11.16. Renewed 23.1.20.

Camphor recovery. E.P. 150,654. See XX.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Vat dyes; Method for printing colour reserves under sulphur colours with —. L. Diserens. Rev. Gen. Mat. Col., 1920, 24, 113—115.

CLOTH is printed with a paste containing per 1000 pts., 150 pts. of Ciba Blue 2B 20% (or other vat dye), 250 pts. of hydrosulphite-sulphoxylate 35%, 250 pts. of British gum, 250 pts. of zinc chloride, and 100 pts. of caustic soda of 38° B. (sp. gr. 1.36), dried, twice steamed in a Mather-Platt for 4 mins., dyed in a bath containing per 1000 pts., 40 pts. of Immedial Carbon BN, 40 pts. of sodium sulphide, 10 pts. of caustic soda of 38° B. (sp. gr. 1.36), and 40 pts. of castor oil soap, then immediately washed, soured, washed, and soaped. Heavy ground shades may thus be obtained. It is important that the printing paste contain the dyestuff in the un-reduced form, and in suitable cases zinc sulphonylate may be used in place of the two separate components; the alkali employed may then be caustic soda, borax, or sodium acetate. Sulphur dyes may be used in the reserve paste if they be only slightly sensitive to zinc chloride. Less satisfactory results are obtained by the use of iron sulphate instead of zinc chloride, but the dyestuff in its reduced form may then be present in the printing paste.

—A. J. H.

Printing resists under formaldehyde-sulphoxylate discharges; Method for —. E. Justin-Mueller. Rev. Gen. Mat. Col., 1920, 24, 129.

PROVIDED that no caustic soda be present, sodium, potassium, or ammonium ferrieyanide is a satisfactory resist. Dyed cloth is printed with a paste containing 200—300 g. of potassium ferrieyanide, 600 g. of water, and 400 g. of soluble starch, dried, printed with a discharge paste containing hyal-dite C.W. extra, dried, steamed in the Mather-Platt, and washed.—A. J. H.

Basic colours; Production of lakes of — with zinc ferrieyanide. E. Justin-Mueller. Rev. Gen. Mat. Col., 1920, 24, 129—130.

COLOUR lakes suitable for printing on paper and textiles are obtained by mixing solutions of a basic dye (1 pt.) and zinc sulphate (2 pts.), and then adding a solution of sodium or potassium ferrieyanide (2 pts.).—A. J. H.

Azo dyestuffs. Justin-Mueller. See IV.

Ammonia in Turkey-red oil etc. Welwart. See XII.

PATENTS.

Printing [half discharge effects on] cotton fabrics. The Calico Printers' Assoc., Ltd., and W. Rouse. E.P. 151,056, 5.6.19.

HALF discharge effects are produced on unprepared fabric or on fabric prepared with Turkey-red oil, β -naphthol, or chlorate mixtures, by printing with a paste containing alkali sulphites with or without the addition of metallic mordants, slop padding with a metallic mordant, drying, and ageing or steaming to fix the mordant. The fabric is then either dunged or otherwise prepared for dyeing and dyed with alizarin or other mordant dyestuff, or tanned and dyed with basic colours. A suitable half discharge paste is made by adding 8 galls. of gum water, 1 galls. of aluminium acetate of 14° Tw. (sp. gr. 1.07), and $\frac{1}{2}$ gall. of turpentine to 4 galls. of a solution containing $\frac{1}{2}$ gall. of caustic soda of 70° Tw. (sp. gr. 1.35) and $\frac{1}{2}$ gall. of sodium bisulphite of 70° Tw. per 2 $\frac{1}{2}$ galls. The aluminium acetate may be replaced by chromium acetate of 40° Tw. (sp. gr. 1.20). If alizarin be used, red and pink effects are obtained.—A. J. H.

Cotton goods; Process for bowking — in one operation. W. Mathesius and M. Freiberger. G.P. 322,992, 15.7.16.

THE goods, which may have previously been steamed, are steeped in a solution of purified used liquor, or a mixture of the same with fresh liquor, containing about 80% of alkali hydroxide, and then bowked in a fresh solution (3 l. per 1 kg. of cotton) containing sodium hydroxide equal to 2.25–3% of the weight of the goods; the liquor is subsequently displaced by a weak alkaline solution, and the goods finally washed with hot and cold water.—L. A. C.

Scouring, dyeing, or otherwise treating with liquor, wool, yarn, or other fibrous material; Apparatus for —. H. Walker. U.S.P. 1,354,081, 28.9.20. Appl., S.12.17.

Jiggers for use in dyeing and other operations [; Brake device for —]. S. Rawlinson, and Mather and Platt, Ltd. E.P. 150,750, 30.6.17.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Electrical precipitation of [sulphuric] acid fog and of dust. A. Delasalle. Chim. et Ind., 1920, 4, 291–316.

AFTER preliminary laboratory research a plant was erected for the Service des Poudres for precipitating the sulphuric acid fog in the fumes from two Gaillard towers. The precipitator was placed between the Gaillard plant and the fan, so that it was always under suction, and the connexions were so arranged that it could be worked in conjunction with either or both of the towers, with or without the coke box, or cut out altogether. A voltage of about 40,000 was employed. The plant consisted of 60 lead pipes, of 3 mm. thickness, 20 cm. diam., and 3 m. length, supported at their upper ends by lead-covered iron collars resting on the floor of the upper chamber. In order to prevent drops of liquid from entering the lower chamber, the pipes were made in two sections, of which the smaller was enclosed by the larger for part of its length, thus forming an annular space which was expanded into a lute, into which the acid fell and which served as a liquid seal to prevent the entry of air. From this seal the acid flowed to a collecting vessel of lead. The electrodes consisted of wire formed like a star and attached to lead-covered iron rods in the upper chamber, terminating in leaden plates in the lower chamber. The fume was made to traverse the precipitator from top to bottom, and its distribution was effected by special devices. In order to obtain acid of a strength of 40° B. (sp. gr. 1.384) maximum, the temperature at which the gases enter the precipitator must not be below 100° C., and they were therefore conducted to the apparatus direct from the coke-box inlet. The average yield from two Gaillard towers, producing 1950 kg. H₂SO₄, excluding the coke-box acid, was 11.5 g. per cub. m. of fume, the latter having a residual acidity after treatment of 1 g., of which 0.18–0.2 g. represented SO₂. Including the amount recovered from the coke-box, which averaged 5 g. per cub. m., the total yield was 575 kg. H₂SO₄ per Gaillard per 24 hrs. The use of the plant with nine Gaillard towers produced an economy of 95,000 francs per annum, and when it was also applied to the recovery of acid from seven 15-ton Kessler systems, the total gain was 200,000 francs per annum. The efficiency may be increased by raising the temperature, but is reduced if the fume velocity is too high, or by presence of nitric acid. Modifications

of the plant were effected as regards increasing the pipe lengths to 3.25 m. and the diameter to 100 mm., and the direction of the fume through the plant was reversed. In connexion with the application of the process to the recovery of dust from pyrites burning, only preliminary investigations have been carried out. A sample of recovered dust gave on analysis: FeSO₄, 24.5; FeO, 25.1; PbSO₄, 39.27; As₂O₃, 8.60; S(sol. in CS₂), 0.24; insoluble matter (Al₂O₃, SiO₂), 2.95%. The dust particles agglomerate and adhere to the collecting electrodes when the temperature does not exceed 250° C. and it is desirable to have as high a temperature as possible, and also to remove the dust mechanically if necessary. Loss of sulphur and dust must be guarded against.—W. J. W.

Persulphuric acid; Decomposition of —. H. Palme. Z. anorg. Chem., 1920, 112, 97–130.

PERSULPHURIC acid, when warmed with sulphuric acid, decomposes with formation of Caro's acid and hydrogen peroxide: H₂S₂O₈ + H₂O = H₂SO₅ + H₂SO₄; H₂SO₅ + H₂O = H₂O₂ + H₂SO₄. Both reactions are unimolecular, and their velocity is increased with increasing concentration of sulphuric acid. The velocity of the first reaction is about 39 times that of the second at 50° C. When persulphuric acid reacts with hydrogen peroxide: H₂S₂O₈ + H₂O₂ = 2H₂SO₄ + O₂, it is probable that Caro's acid is formed as an intermediate product, which then reacts with hydrogen peroxide: H₂SO₅ + H₂O₂ = H₂SO₄ + H₂O + O₂. A method of determining persulphuric acid, Caro's acid, and hydrogen peroxide when all are present in solution depends on the fact that Caro's acid reacts immediately with potassium iodide, hydrogen peroxide much more slowly, and persulphuric acid slowest of all. The solution to be analysed is diluted so as to contain the equivalent of 2.0 g. of potassium persulphate or its decomposition products per l. A 200 c.c. sample is treated with potassium iodide, and the iodine liberated is titrated rapidly with sodium thiosulphate with starch as indicator. The time taken for the titration is observed, and after the end of titration the rate of re-appearance of iodine, due to the slower action of hydrogen peroxide, is noted. A correction can then be applied to the first titration reading, which gives the quantity of Caro's acid present. The sum of Caro's acid and hydrogen peroxide is next estimated on a second sample by treating with potassium iodide and titrating with sodium sulphite. Finally in a third sample, Caro's acid and hydrogen peroxide are reduced by addition of the calculated quantity of sodium sulphite, and the persulphuric acid is estimated by the ferrous sulphate-permanganate method. (Cf. J.C.S., Nov.)—E. H. R.

Electrolysis of solutions of sodium nitrite using a copper anode. F. H. Jeffery. Faraday Soc., June, 1920. [Advance proof.]

THE reactions at the anode are stated to be: the formation of the complex anion Cu(NO₂)₂ from NO₂ ions and the copper; the decomposition of this Cu(NO₂)₂ by the water present giving the basic nitrite, Cu(NO₂)₂·CuO, and nitrous acid; the slow decomposition of the undissociated portion of the nitrous acid formed, giving nitric acid and nitric oxide. Although the presence of nitric acid in contact with the copper anode must give rise to cupric ions if no current were passing, yet, for a current of 0.16 amp., the concentration of such cupric ions as were formed was never sufficient for the deposition of copper on the cathode during electrolyses lasting several hours. The copper reacted with the NO₂ ions to form the complex anion, the anode potential remaining thereby at a low value, rather than with the NO₃ ions, which would have had the effect of raising the anode potential. The result

described is analogous to that taking place during electrolysis with a silver anode in a solution containing NO_2 and NO ions.—B. N.

Ammonium silicate. IV. *Ageing and transformations of silicic acid gels and the process of solution of silicic acid in ammonia.* R. Schwarz and O. Liede. *Ber.*, 1920, 53, 1509—1518.

THE ageing of silica gels when dried at the ordinary temperature consists in the condensation of $(\text{SiO}_2)_x$ to $(\text{SiO}_2)_y$, and this occurs without any change in the appearance of the gel; further changes occur subsequently which lead to the formation of $(\text{SiO}_2)_z$, this point being denoted by the appearance of cloudy particles in the colourless transparent mass. The phenomena at the ordinary and at higher temperature are thus very similar, but much greater dehydration is necessary in the latter case before the end-point is reached. When silicic acid dissolves in ammonia, a colloidal solution of silicic acid is primarily formed which subsequently passes into a molecular solution. (Cf. J.C.S., Nov.)—H. W.

Rubidium (caesium)-silver-gold compound and its application to the microchemical detection of gold, silver, rubidium, and caesium. E. Bayer. *Monatsh. Chem.*, 1920, 41, 223—241.

CHARACTERISTIC crystalline precipitates are formed when solutions of rubidium or caesium chloride are mixed with gold and silver solutions; rubidium-silver-gold chloride, $\text{Ag}_x\text{Au}_{2-x/3}\text{Cl}_3\cdot 3\text{RbCl}$, forms blood-red prisms and platelets, whilst the caesium compound, $\text{Ag}_x\text{Au}_{2-x/3}\text{Cl}_3\cdot 3\text{CsCl}$, crystallises in opaque cubes and stars; the silver and gold are mutually replaceable in these compounds. The crystals are adapted to the microchemical identification of gold, silver, rubidium, and caesium, the smallest quantities recognisable in this manner being 0.1, 0.01, 0.1 and 0.1 microgram, respectively. (Cf. J.C.S., Nov.)—H. W.

Rubidium (caesium)-silver-gold compound and its application to the microchemical detection of gold, silver, rubidium, and caesium. F. Emich. *Monatsh. Chem.*, 1920, 41, 243—252. (See preceding abstract.)

CONTRARY to previous observations (Emich, *Monatsh. Chem.*, 1918, 39, 775), it is now found that the place of rubidium cannot be taken by potassium in this compound, and the value of the method for the detection of caesium and rubidium is thereby greatly enhanced. (Cf. J.C.S., Nov.)—H. W.

Aluminium with sodium peroxide; Ignition of a mixture of — by means of water. O. Olmann. *Ber.*, 1920, 53, 1427—1429.

A MIXTURE of finely-divided aluminium with sodium peroxide, preferably in the proportion of 1:4.3, is readily ignited with feeble explosion by the addition of a few drops of water.—H. W.

Antimony sulphide; Golden —. F. Kirchhof. *Z. anorg. Chem.*, 1920, 112, 67—80.

THE ordinary golden antimony sulphide is described in the literature as consisting of a mixture of antimony pentasulphide and trisulphide with a varying amount of sulphur, according to the method of preparation. It is shown that, in its purest form, golden antimony sulphide contains about 8% of free (extractable) sulphur, and that the residue has the composition $\text{Sb}_2\text{S}_3 + 3\text{ZnCl}_2 + \text{H}_2\text{S}_2 + 2\text{H}_2\text{S}$. The orange-red compound thus obtained contains no free sulphur. It is concluded that antimony pentasulphide does not exist. The

principal constituent of golden antimony sulphide is the tetrasulphide Sb_2S_4 , with a variable quantity, from 0 to 50%, of the trisulphide, Sb_2S_3 , and a variable amount of free sulphur. Sb_2S_4 is to be regarded as antimony thioantimonate, i.e., $\text{Sb}(\text{SbS}_2)$. (Cf. J.C.S., Nov.)—E. H. R.

Stannic and plumbic acids; Salts of —. H. Zocher. *Z. anorg. Chem.*, 1920, 112, 1—66.

SODIUM stannate, prepared by dissolving freshly-prepared stannic hydroxide in hot, concentrated sodium hydroxide, forms a crystalline precipitate, $\text{Na}_2\text{Sn}(\text{OH})_6$, almost insoluble in 6—7 *N* caustic soda solution. A higher hydrate, $\text{Na}_2\text{Sn}(\text{OH})_6\cdot\text{H}_2\text{O}$, was also obtained by precipitation from an aqueous sodium hydroxide solution with alcohol. Three hydrates of potassium stannate were isolated: $\text{K}_2\text{Sn}(\text{OH})_6$, $\text{K}_2\text{Sn}(\text{OH})_6\cdot\text{H}_2\text{O}$, and $\text{K}_2\text{Sn}(\text{OH})_6\cdot 2\text{H}_2\text{O}$. The alkali stannates are unstable and readily decomposed by carbonic acid. Sodium plumbate was prepared by dissolving freshly-precipitated lead peroxide, in small quantities at a time, in strong boiling sodium hydroxide solution. It forms a white, crystalline precipitate, probably $\text{Na}_2\text{Pb}(\text{OH})_6$; analyses always show a slight excess of sodium, $\text{PbO}_2:\text{Na}_2\text{O}=1:1.14$, but this may be due to the presence of carbonate or to adsorption of NaOH . The properties of stannic and plumbic acid are discussed at great length from the colloidal standpoint. (Cf. J.C.S., Nov.)—E. H. R.

Air; Separation of — into oxygen and nitrogen. F. E. Norton. *Chem. and Met. Eng.*, 1920, 23, 511—518.

ANY considerable extension of the use of oxygen for industrial purposes is prevented by the high cost of separating the gas, and this is ascribed to the neglect of sound thermodynamical principles in the processes employed up to the present. The chief defects are the expansion of the compressed air at a very low temperature, which results in the loss of all the work of the primary compression, and the introduction of external heat into the fractionating still. To obtain favourable results the heat of the high-pressure gas should be transferred to the return current of high-pressure gas, and all heat leakage absorbed into high-pressure gas at as high a temperature as possible. All heat carried out of the system should be carried by the smallest stream of low-pressure gas and at the highest temperature possible. Temperature differences between streams of gas should be as small as possible, especially at the cold end of the apparatus. The latent heat of condensation of entering fluids should be exchanged as completely as possible for the latent heat of evaporation of escaping fluids, and the production of liquid air by the cooling effect of nozzles or expansion engines should be avoided. Compression should be effected at the temperature of separation, and all heat rejected to the high-pressure return circuit with subsequent high-pressure expansion. (Cf. Cottrell, J., 1919, 124 *et seq.*)—W. H. C.

Phosphoric acid and its salts. Kolthoff. *See XXIII.*

Ammonia. Hahn and Kootz. *See XXIII.*

PATENTS.

Nitric acid; Process of making —. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 150,836, 17.6.19.

OXIDES of nitrogen from the catalytic oxidation of ammonia are absorbed in nitric acid at -40°C . in a tower or absorption vessel fitted with a revolving shaft and discs. This absorber is cooled by the evaporation of liquid ammonia under reduced pressure, the ammonia gas being returned to the

oxidation apparatus. The nitric acid saturated with oxides of nitrogen passes on through a heat interchanger to the anode chamber of an electrolytic cell to oxidise the nitrogen oxides to nitric acid, and the hydrogen liberated at the cathode (which is immersed in dilute sulphuric acid) and the residual nitrogen from the absorber are utilised in the production of ammonia.—C. I.

Alkali sulphates and sulphuric acid; Manufacture of — from [alkali] bisulphates. Farbenfabr. vorm. F. Bayer und Co. G.P. 297,931, 24.3.16.

An alkali bisulphate is heated in a revolving tube furnace, yielding a light, porous sulphate.

—L. A. C.

Hydrocyanic acid; Method of producing —. G. H. Buchanan, Assr. to American Cyanamid Co. U.S.P. 1,352,655, 14.9.20. Appl., 12.11.19.

CRUDE cyanide containing substantial quantities of lime and calcium and sodium chlorides is dissolved in a refrigerated dilute solution of a mineral acid, more acid being present than is necessary to react with all the impurities. The solution is then passed in counter-current against a source of heat whereby the hydrocyanic acid is distilled.—A. R. P.

Mercuric oxide; Manufacture of — by decomposition of mercurous nitrate. G. Brusa, and V. Borelli & Co. E.P. 150,917, 30.10.19.

Two connected revolving drums are used, one heated and the other cooled. In the former mercurous nitrate is decomposed, and in the latter mercury is acted upon by oxygen mixed with nitrogen peroxide from the first drum. The contents of the second drum are then used as the charge for the first drum, which yields in turn the desired mercuric oxide.—C. I.

Silicate of soda and the like; Method of producing —. W. H. Stanton. U.S.P. 1,352,700, 14.9.20. Appl., 26.1.17.

In the manufacture of sodium silicate a furnace with two hearths is used, which are heated successively by gases of combustion. When the treatment of the charge on the hotter hearth is complete, a new charge is introduced and the direction of the heating gases reversed.—C. I.

Alkaline melts; [Electrolytic] manufacture of reducing —. E. Bergve, Assr. to Norsk Hydro-Elektrisk Kvaelfstofaktieselskab. U.S.P. 1,354,451, 28.9.20. Appl., 10.3.19.

An alkaline melt containing dissolved alkali metal for chemical reductions and syntheses is produced by electrolysing a melt containing an alkali hydroxide, with an anode current density of 20–50 amps. per sq. cm., and a cathode current density of less than 1 amp. per sq. cm.—J. S. G. T.

Alumina and silica; Treating material [e.g., clay] containing —. H. Fleissner. G.P. 322,844, 9.5.19. Conv., 14.4.16.

A MIXTURE of the material (containing 1 mol. of alumina) and calcium sulphate (2 mols.) is heated to a temperature not high enough to liberate sulphur dioxide, i.e., a dull red-heat, with the production of calcium metasilicate (2 mols.) and basic aluminium sulphate (1 mol.). The product is leached with dilute sulphuric acid to dissolve the aluminium sulphate.—L. A. C.

Hydrogen sulphide; Separation of — from gases. A. Krieger. G.P. 322,938, 10.12.18.

THE gases are washed with ammoniacal liquor, fresh water, or a dilute solution of ammonia, at 30°–45° C. Above 45° C. little hydrogen sulphide is absorbed, whilst below 30° C. the absorption of carbon dioxide increases.—J. H. L.

Ammonium chloride; Process for the direct production of — from ammonium carbonate. Wagenmann, Seybel, and Co., A.-G. G. P. 323,038, 20.11.17. Conv., 10.11.17.

DRY or nearly dry hydrogen chloride is led over dry neutral and/or acid ammonium carbonate, or into solutions containing the same in suspension, with or without ammonium chloride in addition. The mother liquor, after separation of the solid product, is treated with ammonia and the carbon dioxide liberated by the action of hydrochloric acid on a previous quantity of the material to produce a fresh suspension of ammonium carbonate.

—L. A. C.

Liquid oxygen; Apparatus for producing —. C. F. and O. J. Crommett, Assrs. to G. L. Cabot. U.S.P. 1,354,380, 28.9.20. Appl., 7.1.14. Renewed 1.7.16.

AIR is forced under high pressure through a coil surrounded by a cooler containing nitrogenous gas at a temperature below freezing point and through a separator. A portion of the cooler extends through the separator, wherein water is frozen out of the air.—L. A. C.

Hydrogen for catalytic reactions; Increasing the activity of —. Berlin-Anhaltische Maschinenbau A.-G. G.P. 301,364, 18.3.16.

INERT hydrogen is activated by the addition of a small percentage of air, oxygen, or other material capable of entering into reaction during its subsequent passage over a catalyst; e.g., water-gas or hydrogen prepared by the action of steam on iron is rendered suitable for the manufacture of tetrahydronaphthalene from naphthalene at 180°–190° C. and 10 atm. pressure by addition of 2% of air or oxygen and passage over hot, finely-divided nickel.—L. A. C.

Zinc chloride; Manufacture of —. C. F. Burgess Laboratories, Asses. of O. W. Storey. E.P. 133,319, 2.10.19. Conv., 26.9.18.

Molybdenum compounds. E.P. 131,898. See X.

VIII.—GLASS; CERAMICS.

Sedimentation [of kaolin]. P. Rena and P. György. Biochem. Zeits., 1920, 105, 133–140.

THE authors find that nearly all of a number of non-electrolytes examined increase the velocity of sedimentation of kaolin; only in the case of compounds virtually insoluble in water could no effect be detected. The magnitudes of the accelerations produced by homolegous compounds increase with the length of the chain. (Cf. J.C.S., Nov.)

—T. H. P.

Lead problem in the ceramic industry. L. Petrik. Sprechsaal, 1920, 53, 405–406.

GLAZES with a lead solubility (Petrik, J., 1914, 80) of less than 1% may be obtained by preparing a lead frit containing a minimum of alkali and no boric acid and a leadless frit containing the requisite quantities of alkali and boric acid and mixing these frits for use. A series of recipes is given, including leadless frits in which pandermite (calcium borate) is used. The solubility of lead glazes containing about 15% of tin oxide is exceptionally low, but they must be completely fused and not merely fritted. It is suggested that standard frits could be prepared more cheaply on a large scale

at lead works than by the potters themselves. Leadless frits might also be made on a large scale, and by the use of mixtures of such frits, together with felspar, quartz, kaolin, pandermite, etc., glazes containing less than 1% of soluble lead could be prepared to meet any required conditions.

Silica bricks for coke-ovens. Enzenauer. See Hb.

PATENTS.

Glass-melting furnaces. L. le B. Mount. E.P. 151,181, 28.11.19.

THE outlets for feeding molten glass to the glass-ware machines are located at the end of the tank adjacent to the recuperator, and consist of holes formed through a raised portion of the bottom of the tank near its sides or end. The outflowing glass is sufficiently fluid without providing any means for heating the glass as it flows out. The products of combustion flow to and fro through the horizontal tubes of the recuperator, and are then led by passages above the crown of the furnace to the chimney. Air passes along a flue below the tank, flows upwards around the tubes of the recuperator, and is then led through passages on the furnace crown placed below the waste gas passages and admitted to the furnace by ports in the neighbourhood of the incoming fuel.—H. S. H.

Coating glass. E. P. 150,598. See Hb.

IX.—BUILDING MATERIALS.

PATENTS.

Concrete; Preparing pumice-stone for use in —. E. C. Bayer. U.S.P. 1,354,233, 28.9.20. Appl., 15.11.19.

PUMICE-STONE is rendered suitable for making light concrete by crushing and heating to a temperature ranging from 1000° C. to the melting point. The fragments contract and become glass-hard, and the outer pores are completely closed through superficial melting, while each separate piece still remains porous inside.—H. S. H.

Cement; Waterproofing —. B. von Leski. G.P. 323,031, 22.11.13.

AMMONIUM resinate is added to cement to make it more impervious to water after setting.—L. A. C.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Cast iron; Influence of nickel and cobalt on the physical and chemical properties of —. O. Bauer and E. Piwowarsky. Stahl u. Eisen, 1920, 40, 1300—1302.

AN addition of up to 1.0% of nickel to cast iron gives favourable results. The resistance to bending is increased by about 30%, the crushing strength increases by 30%, the tensile strength by 25%, and the hardness by 18%. The rate of solution in acid is lowered, although not to the extent expected, the catalytic influence of the graphite being apparently too strong. Nothing is gained by addition of over 1.5% of nickel, as the influence of nickel on the separation of graphite outweighs the refining effect on the ferrite grains. The structure of nickel iron is very similar to that of ordinary grey iron. Cast irons with a nickel content of 1.2% are recommended for machine parts and toothed wheels. With additions of cobalt up to 2% the resistance to bending, crushing strength, and tensile strength decrease, while the hardness

increases to a slight extent. Cobalt hinders the separation of graphite and favours the formation of carbide. The rate of solution in acid is also lowered continuously as the cobalt increases.

—J. W. D.

Tin; Electrolytic refining of —. E. F. Kern. Trans. Amer. Electrochem. Soc., 1920, 38, 187—206. [Advance copy.]

EXPERIMENTS were made with the following electrolytes, each containing 6% Sn: Stannous sodium chloride containing 2.5 g. sodium chloride per 100 c.c.; stannous fluoborate with 5% of free acid; stannous naphthalenesulphonate with 10% of free acid; stannous sulphate with 2.5, 5, and 7% of free acid. The last-named solution gave the best anode deposit when no addition agent was added, but in no case were smooth adherent deposits obtained. When 0.1—0.2% of peptone or gelatin was added to the electrolyte adherent smooth deposits were obtained with the fluoborate and sulphate electrolytes, especially if the solutions were warm (40° C.).—A. R. P.

Brass; Electro-deposition of — from cyanide solutions. A. L. Ferguson and E. G. Sturdevant. Trans. Amer. Electrochem. Soc., 1920, 87—122. [Advance copy.]

EXPERIMENTS on the effect of temperature, current density, and constitution of the anode on the electro-deposition of brass from cyanide solutions led to the following conclusions: The percentage of copper in the deposit is increased by increasing the ratio of copper to zinc in the solution (a Cu:Zn ratio of 4:2 gives a deposit containing 65% Cu), by increasing the temperature, and by the addition of slightly acid substances or of weak acids to the electrolyte, whereas it is decreased by an increase of current density or by the addition of slightly alkaline substances to the electrolyte. Neutral substances have no influence on the electrolysis, but excess of free cyanide decreases the cathode efficiency without increasing the anode efficiency. The most satisfactory deposits of brass are obtained by using a solution containing 35 g. of metals per l. in the above ratio and a small quantity of ammonia, which ensures a bright yellow deposit, together with a current density not greater than 0.3 amp. per sq. dm. Brasses containing 62.3—85% Cu dissolve as such anodically, the efficiency of corrosion being about equal to that of copper. Electrolytically deposited brasses containing 37.6—82% Cu have, in a plating solution, approximately the same potential, which is nearer to that of copper than to that of zinc.—A. R. P.

Lead-bismuth; The binary system —. W. Herold. Z. anorg. Chem., 1920, 112, 131—151.

THE electrical conductivity at 0° and 123° C., the hardness, and the microscopic structure of lead-bismuth alloys were studied with the object of determining the limits of the eutectic range. The conductivity experiments indicated for the limit of solubility of bismuth in lead, 17.5—18.5% Bi, and for the solubility of lead in bismuth, 1.6% Pb. The hardness-composition curve also had a maximum at about 17.5—18.5% Bi, but the interpretation of the hardness results was uncertain owing to the influence on the hardness of previous treatment. The curve had a wave-form between 18.5% and 100% Bi, with an inflexion close to the eutectic point, indicating that the hardness of the eutectic alloys is not derived additively from that of the two series of mixed crystals. The microscopical examination showed that equilibrium is attained in these alloys only after prolonged annealing. The true eutectic limits appear to lie at about 40% Bi on the lead side and 0.2 to 0.5% Pb on the bismuth side.—E. H. R.

Binary systems [alloys]; Relation between chemical resistance and constitution of —. K. Wagenmann. *Metall u. Erz*, 1920, 17, 377—381, 402—408.

FROM consideration of the available experimental data on the resistance of binary alloys to solvents, with or without the presence of atmospheric oxygen, it is concluded that if chemical compounds are possible between the constituents of the alloys a maximum resistance to solution is often found at concentrations corresponding to these compounds. In alloys, the constituents of which form mixed crystals, a maximum occurs at the saturation concentration of these solid solutions, or at least an increased resistance to attack occurs within the range of concentration corresponding to a solid solution of the pure components. Resistance to chemical action is influenced by grain size of the alloy. A minimum in the resistance to attack is obtained with a heterogeneous structure, specially with an eutectic, in the lamellar structure of which electrolytic action probably takes place. In an appendix particulars are given of the methods and apparatus used in the experiments.—T. H. Bu.

Electrical conductivity in metals and alloys at high temperature; Measurement of —. J. L. Haughton. *Faraday Soc.*, June, 1920. [Advance proof.]

AN apparatus for the measurement of electrical conductivity at high temperatures, up to 1000° C., was designed primarily to determine the conductivity of a series of alloys at varying temperatures, with a view to obtaining some information on their constitution. The principle on which the apparatus works is the measurement of the voltage drop along a fixed length of the specimen, through which a constant current is passing. This voltage drop is proportional to the resistance between the points of contact so long as the current is kept constant. To ensure this, the same current is passed through a constantan strip, the resistance of which can be arranged to be of the same order as that of the specimen, and is accurately known, and the voltage drop along this resistance is measured with the same instrument and almost at the same time as that along the specimen. In this way, not only is the constancy of current checked (this being adjusted by means of a rheostat when necessary), but also the instrument which is reading the voltage drop is calibrated directly in some multiple of ohms.—B. N.

Aluminium and sodium peroxide. Ohmann. See VII.

PATENTS.

Electrical [steel hardening] furnaces. L. W. Wild and E. P. Barfield. E.P. 150,793, 4.6.19.

IN furnaces employed for hardening steel by means of a bath of molten salt contained in a silica crucible or the like (E.P. 112,731; J., 1918, 154A), the silica crucible is replaced by a silica furnace lining within which is a loosely fitting metal (e.g., iron) pot for the reception of the molten salt having a coefficient of expansion approximating to that of the salt.—J. S. G. T.

Iron silicide; Process for producing articles of —. N. Petinot. U.S.P. 1,346,333, 13.7.20. Appl., 18.8.19.

ARTICLES of iron silicide, resistant to corrosion, are made by casting the alloy in graphite moulds.—B. N.

Alloy of iron, chromium, and titanium, and [electrical] process for the production thereof. Method for making chrome-steel. H. C. Sicard, Assr. to United States Ferro-Alloys Corp. U.S.P. (a) 1,346,343 and (b) 1,346,344, 13.7.20. Appl., 18.8.19.

(A) CHROMIUM ore, rutile, and scrap iron are mixed

with carbon sufficient to reduce the chromium and titanium oxides, and also to form by combination with the chromium, titanium, and iron a complex carbide in the finished alloy. The mixture is then smelted in an electric furnace. (b) Chromium steel is made by adding to molten steel an alloy of iron, chromium, titanium, and carbon.—B. N.

Steel; Manufacture of —. G. B. Waterhouse. U.S.P. 1,352,710, 14.9.20. Appl., 31.7.19.

THE physical structure of steels with a maximum content of 0.25% C is improved and the distribution of sulphur rendered more uniform by treating the molten steel with such a quantity of silicon that the silicon content of the resulting metal is not materially increased.—A. R. P.

Electrolytic soft iron; Production of —. M. Schlötter. G.P. 308,543, 7.2.18.

FERRIC salts formed during electrolysis are reduced to ferrous salts by the addition of hydroxylamine, hydrazine, compounds of the same, or carbon-free electrolytic iron. Iron with a Brinell hardness of 50—60 is thus obtained.—L. A. C.

Ingot iron and steel and other metals; Removing oxygen, sulphur, and phosphorus from molten —. Deutsch-Luxemburgische Bergwerks- und Hütten-A.-G., and S. Hilpert. G.P. 322,988, 22.9.16.

ALUMINIUM carbide is added to the molten metal, and, if necessary, owing to the absence of slag, e.g., in ingot moulds, other carbides, such as calcium carbide, are also added so that a fusible slag is produced.—L. A. C.

Molybdenum compounds; Extraction of — from yellow lead ores [wulfenite]. Deutsche Molybdaen-Werke, G.m.b.H. E.P. 131,898, 27.8.19. Conv., 2.10.16. Addn. to 131,897.

FINELY powdered wulfenite is digested hot or cold with a solution of ammonium or alkali sulphide or fused with alkali sulphide or with alkali sulphate and carbon, the amount of the sulphur compound used in any case being less than that required to transform the molybdenum into alkali sulphomolybdate, so that any of the latter compound first produced is changed into molybdate by the excess of ore present.—A. R. P.

Electrodes for electric welding. A. Le Chatelier. E.P. 147,270, 14.4.19.

A COATING for electrodes for electric welding consists of a mixture of substances, preferably anhydrous and only containing a small proportion of oxides decomposable by heat, refractory enough to prevent too rapid fusion of the coating and giving a fusible and acid slag. It contains from 33 to 67% of silica (or equivalent quantities of native silica or silicates), 23 to 62% of iron oxide (or equivalent quantities of suitably ground and dried iron ores), 5 to 22% of lime as carbonate (or equivalent amounts of carbonates of other alkaline earths, including magnesia and alumina) in a finely powdered state with addition of carbon. A small quantity of another metallic oxide, such as manganese or nickel oxide, may be added to the iron oxide. The mixture is made into a paste by means of a binding material such as a solution of dextrin or alkali silicates, or by a binding medium dissolved in a liquid which does not contain water.—B. N.

Electrodes for use in electric welding. A. C. Hyde. E.P. 148,645, 1.5.19.

AN electrode, for the electric welding of iron or steel, is composed of iron or steel, and a deoxidising material, such as silicon or aluminium, which has been introduced into the iron or steel before it is formed into an electrode.—B. N.

Welding-rod. R. F. Russell, Assr. to Air Reduction Co. U.S.P. 1,352,534, 14.9.20. Appl., 24.6.19.

A RARE-EARTH metal is incorporated in a welding-rod composed mainly of iron, to prevent the formation of deleterious oxides and nitrides when the rod is melted to form a weld.—J. S. G. T.

Welding steel; Electrically —. J. W. Plant. U.S.P. 1,354,266, 28.9.20. Appl., 29.1.19.

AN arc is struck between the part to be welded and an electrode of corresponding material, within a welding chamber, in which a non-oxidising atmosphere is maintained.—J. S. G. T.

Alloy for electric welding. E. J. Kingsbury. U.S.P. 1,350,317, 24.8.20. Appl., 20.11.19.

AN electric welding alloy contains iron, carbon, manganese, and vanadium.—B. N.

Electro-deposition of metals. J. H. B. Jacobs. E.P. 147,338, 23.12.19.

THE apparatus comprises a revolving drum, and an anode formed in two parts, each of which is supported on a carrier of wood, or like non-conducting member, inserted into the drum through openings in each end. A distributor is fitted on the drum for supplying current to the cathode. The electroplated articles are removed from the drum through openings in the ends.—B. N.

Copper plates for process printing; [Electrolytic] manufacture of —. S. O. Cowper-Coles. E.P. 151,027, 5.3.19.

COPPER is electrolytically deposited upon cathode plates suspended by connecting rods attached to eccentrics, so that an oscillating or reciprocating motion is imparted to the plates. A vertical paddle at one or both ends of the depositing vat causes the electrolyte to pass with a velocity of 500 to 600 ft. per min. over the surface of the cathode plates, the circulating electrolyte being also passed continuously through an external filter.—J. S. G. T.

Zinc; Recovery of — by electrolysis. R. H. Stevens, Assr. to Electrolytic Zinc Co. of Australasia Proprietary, Ltd. U.S.P. 1,347,189, 20.7.20. Appl., 11.11.19.

THE cathode is provided with a protective coating above the normal solution level, by first carrying out a preliminary electrolysis with the cathode immersed to substantially a line immediately below the supporting bars, the cathodes having wooden strips fixed at or about the normal solution level which prevent the deposition of zinc under them. The strips are then removed and the electrolysis continued in the ordinary way in cells with the solution at normal level, whereby the zinc deposited subsequently can be stripped along the line of weakness at or about the solution level.—B. N.

Metals; Method of and apparatus for reduction of — to powder. J. P. Mellor. E.P. 150,490, 4.7.19.

THE metal is heated to a temperature approaching its volatilisation point (in the case of zinc, 700°–800° C.), and poured in a thin stream upon a flat jet of high-pressure steam.—B. M. V.

Furnace; Rotary electric — for continuously melting zinc dust. C. E. Cornelius. G.P. 322,808, 21.10.19. Conv., 20.8.19.

THE zinc dust is introduced into the middle portion of the furnace.—L. A. C.

Electrolytic pickling process. J. Coulson, Assr. to Westinghouse Electric and Manufacturing Co. U.S.P. 1,347,897, 27.7.20. Appl., 3.11.17.

COPPER objects are pickled electrolytically by subjecting them as cathodes to the action of an elec-

tric current, so as to dissociate the surface oxide, and simultaneously recover any copper which is set free.—B. N.

Reverberatory furnace [; Method of charging a —]. H. L. Charles. U.S.P. 1,351,835, 7.9.20. Appl., 30.8.17. Renewed 23.1.20.

THE ore charge is dropped through the roof on to the hearth so as to form mounds at frequent intervals.—B. M. V.

Copper and other metals; Process and apparatus for reclaiming and refining —. A. R. Partidge. U.S.P. 1,352,912, 14.9.20. Appl., 15.9.19.

MATERIAL from which copper or other metals are to be reclaimed is heated to the melting temperature, and the temperature is then lowered to cause the materials to "sweat" and trickle down an inclined surface, the trickling material being purified by treatment with oxygen.—L. A. C.

Molten metal; Process of treating —. O. Thiel, Assr. to The Chemical Foundation, Inc. U.S.P. 1,353,126, 14.9.20. Appl., 28.12.16.

SLAG is removed by overflow in any desired quantity from the surface of a bath of molten metal by adding a corresponding amount of unmelted metal of the same kind to the melt.—A. R. P.

Zinc-lead alloy. H. Falkenberg. G.P. 322,960, 25.4.19. Addn. to 300,111 (*cf.* J., 1919, 292A, 374A, 869A).

THE alloy contains up to 5% Fe, less than 2% Al, and about 1.5% Cu.—L. A. C.

Electric furnace. R. Steiger, Assee. of H. Blumer. E.P. 125,391, 7.4.19. Conv., 8.4.18.

ELECTRIC furnaces, using polyphase current, are operated with combined arc and resistance heating, and are provided with an electrode for each phase of the system above the surface of the bath and oppositely arranged electrodes in the hearth. The hearth electrodes and one of the upper electrodes are connected with the same point in the supply system. The upper electrodes are switched in during those stages of the working in which the quietest possible behaviour of the material under treatment is required, with a more or less energetic surface heating, whilst in those stages of the working in which an energetic permeation of the whole of the material in the direction of its depth is necessary, one of the upper electrodes is switched out and the hearth electrodes are switched in.

—B. N.

Resistance for electric furnaces. Electric furnace. E. Piquerez. E.P. (A) 139,448, and (B) 132,232, 18.7.19. Conv., (A) 26.2.19, (B) 2.9.18.

(A) ELECTRIC resistance elements, in the form of rods with greater cross-section at the parts where the current leads are attached, are provided with a deposit of metal of low electrical resistance at the enlarged portions, the deposit being formed on the outside of the rod or in a hole bored in the rod. The deposit may be covered with a coating of enamel of high melting point. (B) The heads of the resistance elements are situated in spaces provided between the outside of the furnace walls and an outer casing, through which spaces air currents can flow for cooling the heads.—B. N.

Electric furnaces; Transformation of polyphase currents, particularly for use in —. J. Bibby. E.P. 149,049, 2.5.19.

POLYPHASE currents are transformed electrically by supplying three-phase current to five static transformers having transformer ratios of 0.886, 1.22, 1.67, 1.22, and 1.0 respectively, the primary windings being so connected with the supply mains and the secondary windings with load terminals, that eight-phase currents having eight voltages progressively 45° apart are obtained. The eight-phase current is supplied to an electric furnace having eight octagonally-spaced electrodes. By using the larger number of electrodes the heat can be generated more effectively and more uniformly than hitherto.—B. N.

Electric furnace. E. L. Smalley. U.S.P. 1,346,854, 20.7.20. Appl., 21.10.19.

THE furnace is provided with a series of heating units, supported by elements which may be shifted horizontally, whereby the units are rendered both adjustable and renewable.—B. N.

Furnace; Electric — for heating ribbons and bars. Double hot-chamber [electric] furnace. O. A. Colby, Assr. to Westinghouse Electric and Manufacturing Co. U.S.P. (A) 1,347,895 and (B) 1,347,896, 27.7.20. Appl., (A) 16.9.18 and (B) 14.12.18.

(A) A HEATING chamber is provided with a roof forming a resistor, and a supporting means associated with the resistor to provide the heating chamber with a rectangular cross-section, the resistor being adapted to be made hotter at one portion than at another. (B) The furnace is provided with two associated heating chambers, a pre-heating chamber, and resistors for supplying heat to all the chambers.—B. N.

Furnace; Electric —. Method of oxidising materials [steel billets] in electric furnaces. W. S. Mayer and W. C. Kennedy. U.S.P. (A) 1,350,876 and (B) 1,350,877, 24.8.20. Appl., (A) 15.12.16 and (B) 17.3.17.

(A) AN electric resistance furnace is provided with a wall including a number of resistance units, each comprising a block of refractory material and a resistance element. (B) Metals, e.g., steel billets, are oxidised on the surface to remove surface imperfections by heating in an electric furnace to a temperature sufficient to form a scale, a regulated predetermined amount of oxygen being supplied to the heated material.—B. N.

Electric-arc furnace. F. von Schlegell. U.S.P. 1,352,541, 14.9.20. Appl., 28.1.20.

THE electrodes are supported in contact with each other in such a manner that they can move relatively to one another under the influence of the magnetic field set up when a current flows through the electrodes, so that the electrodes are in contact when no heating current is flowing, and an arc is struck automatically when current is supplied.

—J. S. G. T.

Electrodes; Manufacture of carbon —. C. H. Thompson. E.P. 147,247, 8.3.19.

THE firing or burning of the electrodes is effected in a muffle or the like without the packing materials hitherto employed, and the material is subjected during the firing to the action of producer gas. (Reference is directed, in pursuance of Sect. 7, Subsect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 9835 of 1888, 18,263 and 23,830 of 1899, and 371 of 1900; J., 1889, 697; 1899, 1112; 1900, 355, 911.—B. N.)

Electric [dynamo] brushes; Material for —. A. E. White. From Becker Bros. E.P. 150,765, 29.4.19.

CEROUS oxide, produced electrolytically, either alone or mixed with other oxides, by electrolysis of sodium chloride solution, using an anode of copper or a copper alloy, is mixed with an excess of graphitic carbon and reduced in a closed chamber in a reducing atmosphere, and the resulting mixture of graphite and copper or copper alloy is employed for making electric dynamo brushes and the like.—J. S. G. T.

Negative plate for (A) electric batteries or (B) electric accumulators, and process for making it. A. Pouchain. E.P. (A) 150,810 and (B) 150,811, 6.6.19.

(A) An amalgamated plate of zinc is employed as cathode in an electrolytic bath containing water slightly acidified with sulphuric acid to which are added about 5% of magnesium sulphate, 5% of mercuric sulphate, and preferably a small amount of ammonium sulphate. The current density is adjusted to about 2 ampères per sq. dcm. The plate is preferably perforated, and on removal from the bath is dried at a gentle heat and wrapped in a sheet of greased paper. (B) A supporting plate of a non-metallic electrically conducting material, preferably ribbed and perforated, is employed as cathode in a bath containing a salt of magnesium, a salt of mercury, and a salt of zinc, until a deposit of zinc about 1 mm. thick is obtained. If desired the support may first be covered with a very thin layer of copper electrolytically deposited.

—J. S. G. T.

Electrolytic cell. R. M. Shaw. U.S.P. 1,346,849, 20.7.20. Appl., 29.7.18.

THE apparatus comprises a receptacle forming one electrode, and a diaphragm carried by a removable member which is supported upon the receptacle. A second removable member, also supported upon

the receptacle, carries an electrode which is insulated from the receptacle and extends within the diaphragm. Means are provided for separately conducting the gases from the receptacle.—B. N.

Electrolytic apparatus. Apparatus for [electrically] treating liquids with gases. W. E. Greenawalt. U.S.P. (a) 1,317,088 and (n) 1,317,089, 20.7.20. Appl., (a) 1.2.17 and (n) 25.3.15. (n) Renewed 27.2.20.

(A) A chamber provided with a gas inlet and outlet is adapted to contain a liquid and to confine a gas over the liquid. Means are provided for causing the gas to flow from the inlet to the outlet, and for taking the gas from above the liquid and forcing it through the liquid, whilst passing an electric current through the liquid. (n) A stationary chamber is provided with gas and liquid inlets and outlets, and with means operated within the chamber for submerging some of the gas in the liquid. Electrical means are used for causing a chemical reaction between the liquid and the gas.—B. N.

Electrolytic apparatus. W. E. Greenawalt. U.S.P. 1,353,995, 28.9.19. Appl., 7.1.19.

An electrolytic vessel comprises an electrolyser and a chamber in which a relatively large volume of electrolyte is kept under continuous treatment with a reducing gas which is confined above the surface of the electrolyte. This chamber is provided with inlets and outlets for the gas and electrolyte. The reduced electrolyte flows from the chamber to the electrolyser, oxidised electrolyte flowing in the reverse direction, and the rate of flow and time of treatment in the electrolyser are so regulated that the oxidation and reduction processes are maintained within predetermined limits.—J. S. G. T.

Electrolytic cell. H. I. Allen and K. R. Fox, Assrs. to Electron Chemical Co. U.S.P. 1,349,597, 17.8.20. Appl., 2.4.19.

An electrolytic cell comprises an upper closed free-board section, suspended from which, by a liquid-tight joint, is a metallic basket-like cathode, provided with perforated side, bottom, and end walls furnishing active faces. A porous diaphragm covers the inner faces of the cathode. A tubular anode, occupying the space within the cathode, is spaced from the inner faces of the end, bottom, and side walls, the upper edges of the anode being free so as to permit the electrolyte to flow over them. The free-board section rests on a tank, with the cathode suspended in it, but spaced from the walls, and means are provided for withdrawing the effluent from the tank so as to prevent the submergence of the cathode, the parts being so arranged that the level of the electrolyte in the free-board section may be above the top of the tank so as to increase the hydrostatic pressure.—B. N.

Electric battery. O. E. Ruhoff, Assr. to French Battery and Carbon Co. U.S.P. 1,352,987, 7.9.20. Appl., 21.11.18.

The battery contains a depolarising mixture consisting of 50 pts. of manganese dioxide, 49 pts. of carbonaceous material, 10 pts. of ammonium chloride, and 12 pts. of a zinc chloride solution of 45° B. (sp. gr. 1.45), the manganese dioxide being of such a character as to yield no trace of poisonous metal when leached with a 30° zinc chloride solution saturated with ammonium chloride.—J. H. L.

Electric battery; Oil-protected — and method of producing the same. O. E. Ruhoff, Assr. to French Battery and Carbon Co. U.S.P. 1,352,831, 11.9.20. Appl., 28.1.19.

Is an electric battery constituted of carbon, zinc, electrolyte, and depolarising agent, a thin coating

of oil is employed to protect the zinc from chemical action on open circuit.—J. S. G. T.

XII.—FATS; OILS; WAXES.

Oil and fat preparations [Turkey-red oil etc.]; Determination of ammonia in —. N. Welwart. Chem.-Zeit., 1920, 44, 719.

To determine ammonia in Turkey-red oil and similar products in which free acidity has been neutralised with ammonia, the sample is mixed with water and an excess of calcium chloride solution, a few pieces of pumice-stone and a sufficient quantity of sodium hydroxide are added, and the mixture is distilled, the ammonia being collected in standardised acid. The calcium soaps formed do not froth during the distillation. Light mineral oils, if present, may pass over into the distillate, but do not interfere with the determination. Methods which depend on the extraction of the ammonia by shaking the oil with dilute acid and subsequent distillation of the acid extracts with sodium hydroxide are not always trustworthy, since certain sulphonated oils contain the ammonia in such combination that it is not extracted even by boiling with acidified water.—W. P. S.

Oxidation of paraffin wax. Kelber. See IIa.

PATENTS.

Oils; Process and apparatus for hydrogenating —. J. S. Withers. From National Electro-Products, Ltd. E.P. 150,802, 5.6.19.

A tube enclosing a shorter concentric tube passes through the top and bottom of a cylindrical tank, and extends for some distance below the bottom of the tank. Two sets of openings are provided in the outer tube, near the top and bottom of the tank, the openings near the top being adjustable. A mixture of oil and catalyst is fed into the tank near the bottom, and hydrogen is pumped through a pipe passing in at the lower end of the outer tube and extending into the inner tube. The temperature is maintained at 200°–250° C. by an electric coil situated just above the hydrogen inlet, and the pressure at about 80 lb. per sq. in. The stream of hydrogen forces the oil upwards through the inner tube; residual hydrogen is drawn off at the top of the tube and is returned to the hydrogen inlet, and the oil flows through the upper set of openings into the tank, fresh oil flowing into the annular space through the lower set. The hydrogenated oil passes out at the top of the tank and flows around the inlet tube to preheat the fresh oil supply.—L. A. C.

Lanolin; Method of making —. W. C. Broadgate, Assr. to F. W. Harmon. U.S.P. 1,354,376, 28.9.20. Appl., 26.3.19.

AN alkali peroxide is added to wool grease which is heated to produce a thin, smooth product, and the mixture, after agitation, is allowed to stand until the grease is bleached. The lanolin is then separated by centrifuging.—L. A. C.

Oils and fats; Deodorisation of —. W. Alexander. G.P. 322,347, 4.4.19.

THE oil or fat is allowed to flow downwards through a tower packed with inert material, whilst steam is passed upwards through the tower.—J. H. L.

Fat and oil; Countercurrent process for extracting — from raw materials. H. Bollmann. G.P. 322,446, 30.5.18. Addn. to 303,846 (J., 1920, 459 A).

THE material, e.g., cereal embryos, in containers, is moved first downwards and then upwards through the chamber, and the solvent is led through the material in the opposite direction to the latter during its upward travel and in the same direction as the material during its downward travel.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Colour classification; Practical application of Ostwald's scheme of —. A. Wirth. Chem.-Zeit., 1920, 44, 737—738.

AN apparatus is described for determining the black, white, and coloured constituents in pigments in accordance with Ostwald's scheme of classification into 680 colours (J., 1919, 914 A). As a rule the colours of oil pigments can be readily matched, but the proportion of white is generally less, and that of the black higher, than the calculated amounts. Difficulties are only experienced with pigments containing less than 2% of colour. By the use of the five colour tones in Ostwald's diagrammatic circle, and the addition of suitable proportions of black and white, any of the other colour tones may be obtained in a state of sufficient purity.—C. A. M.

PATENTS.

Potentially-reactive [resinous] composition and process of making same. L. H. Baekeland, Assr. to General Bakelite Co. U.S.P. 1,354,154, 28.9.20. Appl., 31.10.19.

THE composition contains a phenol resin and a methyleneamine-phenol.—L. A. C.

Paint vehicles; Manufacture of — from mineral oils. J. Soukup. G.P. 321,828, 1.11.18. Conv., 15.5.18.

VASELINE, purified and dehydrated by heating with slaked lime, is heated with an oxidising agent such as manganese dioxide or lead peroxide, boiled with resin, and, after standing, is diluted and separated from any sediment.—L. A. C.

Varnish; Manufacture of — from unsaponifiable coumarone resins without use of benzol as solvent. W. Schwarz. G.P. 322,802, 14.6.18.

COUMARONE resin is purified by treatment with sulphuric acid, and the hot mixture is treated with air or oxygen under pressure. The resinous product is emulsified with water at 70°—100° C., and

a solution of glue and potassium bichromate is added to prevent separation of the emulsion.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Methods of preparation of plantation —. Causes of the inferiority of plantation scrap rubber. Third report of the Ceylon Rubber Research Scheme. Indiarubber J., 1920, 60, 673—674.

SCRAP rubbers generally give low values for ultimate tensile strength and elongation, the inferiority being due to the presence of foreign matter not removed by washing; the mineral constituents, particularly the particles of sand, are mainly responsible. Investigations of the effect of smoking the rubber, of different methods of drying, and of various modes of preparation confirm those of earlier workers.—D. F. T.

Rubber; Determination of true free sulphur and the true coefficient of vulcanisation in vulcanised —. W. J. Kelly. J. Ind. Eng. Chem., 1920, 12, 875—878.

ONE g. of the ground rubber is extracted continuously with acetone for 16 hrs., the acetone solution is evaporated, the residue dried at 65° C. for 30 mins., and then treated in a flask with 50 c.c. of 95% alcohol saturated previously with sulphur. The flask and its contents are weighed, heated to 60° C., cooled, and any loss in weight adjusted by the addition of alcohol. After 24 hrs. the solution is decanted, the insoluble residue of sulphur washed with sulphur-saturated alcohol, dried, and weighed. Sulphur which is combined with resins, proteins, etc., and which is soluble together with the free sulphur in acetone, remains soluble in the alcohol, whilst the true free sulphur is insoluble in the latter solvent. The sulphur which is not extracted by acetone is not wholly combined with rubber, a part being also present in combination with resins and proteins; the sulphur thus combined should not be included in the value for the coefficient of vulcanisation. If the sample (1 g.) after extraction with acetone for 16 hrs. is dried, boiled with 5% alcoholic potassium hydroxide solution for 8 hrs., and then extracted with alcohol for 16 hrs., the alcoholic (alkaline and neutral) extracts will contain the sulphur which is combined other than with rubber. The quantity of this form of sulphur is ascertained by evaporating the united alcoholic extracts, oxidising the residue, and precipitating the sulphuric acid as barium sulphate.—W. P. S.

PATENTS.

Vulcanised product; Production of a soft, elastic, and ductile —. Production of a ductile, tenacious, and elastic vulcanised product. Farbenfabr. vorm. F. Bayer und Co. G.P. (A) 303,984, and (B) 305,667, 20.2.17.

XV.—LEATHER; BONE; HORN; GLUE.

Tannins. Y. *Phloroglucinol-tannins and catechins. Constitution of gambier catechin.* K. Freudenberg. Ber., 1920, 53, 1416—1427.

GAMBIER catechin has been considered by Kostanecki to be a derivative of ethyldiphenylmethane, mainly on account of its reaction with diazonium salts. By the action of sodium and alcohol on its tetramethyl ether and subsequent methylation, a crystalline pentamethyl ether is produced which Kostanecki regarded as 3-ethyl-2,4,6-trimethoxyphenyl-3',4'-dimethoxyphenylmethane, but which is now shown to be 2,4,6,3',4'-pentamethoxy- α -diphenylpropane. Hence, like the nearly related flavone dyes, anthocyanidins and phenyl styryl ketones, gambier catechin must have an α -diphenylpropane skeleton. (Cf. J.C.S., Nov.)—H. W.

Tannins; Electro-chemistry of the —. G. Grasser. Collegium, 1920, 17—29, 49—69, 137—152, 200—207, 277—290, 332—341.

ELECTRO-OSMOTIC experiments showed that most tannins have a negative charge, as shown by anodic migration. In some cases the migration was sluggish or indefinite, and normal cataphoresis was only obtained after adding acids, preferably acetic acid. The only exception was quebracho, which migrated to the cathode. The presence of cations prevents tannin migration. The whole solute migrates in the case of galls, pine bark, maletto, and tannic acid in acetic acid, quebracho in sodium hydroxide, quebracho-calcium compound, quebracho-methylene blue compound, and mixtures of quebracho with sulphite-cellulose extract and neradol D. In several instances there is simultaneous decomposition of the tannins, especially in presence of electrolytes. Mangrove and catechu were found to be sodium salts of the fundamental tannins or tannin dyestuffs, hence their feeble tanning action, dark colour, and good solubility. From both there was obtained at the anode a brown base-free precipitate which was redissolved on addition of alkali. Electro-osmosis of soluble tannins generally results in decomposition, with the formation of soluble products which separate at the anode or cathode, or accumulate in the residue of the treated solution. Decomposition is frequently indicated by the qualitative chemical properties which differ from those of the original tannin: in some cases products are formed which do not precipitate gelatin. In most cases the electric current produces insoluble compounds which are sometimes soluble, but usually insoluble, in alkali, and which are sometimes formed so quickly—e.g., with oak bark—that it is impossible to obtain a dialysate containing any dissolved matter. Electro-osmosis can be employed to separate two qualitatively different tannin substances from a tanning material; this was effected in the case of valonia and oak bark. From knopperrn, on the other hand, two tannin substances were separated, of which one possessed no astringent properties. The separation of substances which no longer gave the tannin reaction but functioned as dyestuffs similar to indicators was effected with catechu, mangrove, and particularly with maletto. The purification and isolation of tannins from their extracts or adsorption compounds does not appear possible by the aid of electro-osmosis owing to the secondary changes. The detection of mangrove and quebracho in other extracts, and of sulphite-cellulose, neradol D, sulphite, bisulphite, and sugar by electro-osmosis was found possible. The experimental results show that the passage of an electric current through tan liquors should facilitate tanning, and there would seem to be special advantages in using weak tan liquors.—D. W.

Synthetic tannins. G. Grasser. Collegium, 1920, 234—255.

THE precipitation of gelatin and the absorption of a substance by hide powder are not necessarily accompanied by tanning properties. Thus, hydroxynaphthylmethanesulphonic acid precipitates gelatin, but it has no tanning action on pelt. Sodium diresylmethanedisulphonate does not precipitate gelatin nor tan pelt, but it is absorbed like tannin by hide powder. *o*-Nitrophenol does not precipitate gelatin, but it has a tanning action on both pelt and hide powder. All mono- and polyhydric phenols, after conversion into soluble sulphonic acids, can be converted into true tanning substances by condensation with substances capable of abstracting the elements of water. The condensation can be effected first and sulphonation afterwards, or *vice versa*. Alkaline solutions of phenol can be similarly condensed with materials capable of abstracting the elements of water, with formation of soluble products. Among the substituted phenols thio-, bromo-, chloro-, nitro-, and amino-derivatives give very similar tannins. Quinones are tanning materials. Aromatic di-alcohols condense very readily and give good tannins. All the aromatic acids appear to give soluble tannins of technical value after condensation and sulphonation; in some cases the soluble alkali salt must be condensed with formaldehyde to obtain a tanning material. Diphenyl derivatives and compounds containing condensed nuclei usually possess tanning properties if they contain the above-mentioned groups. The condensation can always be effected by means of formaldehyde; in a few cases with acetaldehyde and benzaldehyde. Other dehydrating agents, such as sulphur chloride, and phosphorus compounds generally effect condensation very readily, but secondary reactions impart a bad colour to the products, rendering them unsuitable for tanning purposes.—D. W.

Artificial tannins; Detection of —. R. Lauffmann. Collegium, 1920, 169—171.

THE indophenol reaction (Seel and Sander, J., 1916, 1028) is not a sure guide to the detection of synthetic tannins, but negative results with it prove their absence. The best method of carrying out the test is as follows:—10 g. of finely divided leather is treated with 100 c.c. of 2% caustic soda solution for 1 hr. with occasional shaking, the liquor filtered, and the leather residue treated with a further 100 c.c. of 2% alkali for 1 hr., filtered off, and the solution added to the previous filtrate. The liquid is neutralised with sulphuric acid, evaporated to dryness, and the dry residue heated with 20 c.c. of caustic potash solution (1:1). The product is treated with dilute sulphuric acid, nearly neutralised with sodium hydroxide, 100 c.c. of 10% ammonia solution added, and the whole allowed to cool. The liquid is extracted with ether, and after evaporating the ether the extract is dissolved in alcohol and treated with a few drops of concentrated ammonia, 2 drops of 0.6—0.7% aqueous solution of *p*-phenylenediamine hydrochloride, and 5% potassium ferricyanide solution. A positive indophenol reaction is shown by a blue or greenish-blue colour.—D. W.

Quebracho tannin. W. Moeller. Collegium, 1920, 106—109.

THE peculiar properties of quebracho extracts are due to the presence of predominating quantities of peptonised matter, or phlobaphenes. The extracts are derived from the heart wood. The sapwood differs from this in colour and composition, containing tans 6.4%, non-tans 2.2%, insoluble matter 76.4%, water 15.0%. The ratio of tans to non-tans is only 3:1, whereas in the heart wood it is 10:1, with a tannin content of 20%. The tannins in the

sapwood partake more of the nature of pyrogallotans. There are certain brighter parts in the heart wood which have evidently been protected from the oxidising and condensing influences of sap. These portions contain tans 7.8%, non-tans 1.7%, insoluble matter 77.1%, and water 13.4%, and give a dirty-blue colour with iron alum, a precipitate with bromine water, and a distinct precipitate with lead acetate and acetic acid; the ethyl acetate number is 54.24. Almost all these reactions and analytical constants differ from those usually associated with quebracho wood.—D. W.

Tannin analysis; Proteolytic factor in —. W. Moeller. *Collegium*, 1920, 307—319, 374—381.

Some substances which are not absorbed by hide powder alone are absorbed by hide powder from mixtures. Hide powder or pelt is considered to consist of an intact portion of micells and an easily decomposed portion of interfibrillary tissue which may be present in all stages of decomposition down to amino-acids. Hence a portion of the hide powder will be dissolved by water, and the author has determined this by weighing and by nitrogen estimations. The nitrogen content of the aqueous extract is an index of the amount of solubilised hide substance. Determinations with a large number of tanning materials have shown that large amounts of hydrolysed hide powder pass into the non-tan solutions in both the shake and filter bell methods of tannin analysis and adversely affect the tannin estimation. An adsorbent is required which will be resistant to the hydrolytic effects of the different tannins. Light chroming of the powder does not reduce the amount of hydrolysis, and either a stronger preliminary tannage with vegetable or mineral tanning agents should be given or some mode of preservation resorted to. Parker has suggested the use of formaldehyde, but this is no better than other tanning solutions. This hydrolysis is part of the tanning process and must be taken into consideration in the valuation, analysis, and purchase of tanning materials. The hydrolytic effects of different tannins at various concentrations over long periods of time on the pelt are not comparable with the effect of very dilute solutions on hide powder. In leather manufacture the tanning liquors are always more saturated than the pelt, whereas in tannin analyses the hide powder is always in great excess and completely detannises the solution. The amounts of hide substance found in the non-tans in both the shake and filter bell methods are on the average between those found in the blank determinations with unchromed and chromed hide powder.—D. W.

Pelt analysis. [Estimation of lime.] G. Grasser. *Collegium*, 1920, 80—81.

The damp pelt is pressed between dry cloth, cut into strips, and 5 g. heated with 3 c.c. of concentrated nitric acid and 50 c.c. of distilled water in a large covered beaker. In 10 mins. the pelt dissolves to a clear solution which is neutralised with ammonia and the calcium precipitated with ammonium oxalate. The calcium oxalate is ignited and the calcium determined as oxide.—D. W.

Aldehyde tannage; Formaldehyde titration of hide powder and —. O. Gerngross. *Collegium*, 1920, 2—11.

The author confirms Stiasny's statement (J., 1908, 113, 580) that hide powder which has been treated with formaldehyde adsorbs less acid than untreated hide powder. The diminution in the acid adsorbed shows no regularity with different acids, and it is concluded that the formation of acid from formaldehyde, as suggested by Moeller (*Collegium*, 1919,

270), does not take place. With increased hydron concentration the reaction between the hide powder and the formaldehyde is suppressed. The decreased acid adsorption of hide powder which has been treated with formaldehyde is not a proof of the presence of free amino groups, but only establishes the presence in collagen of basic groups capable of reacting with formaldehyde. Moeller (J., 1920, 36 A) claims that the hide fibres in aldehyde-tanned leather are surrounded by a sheath of formaldehyde polymers, which prevent the fibres from reacting with acid. If this were the case the hide fibres should likewise be protected from alkalis and show decreased alkali adsorption, whereas experiments show a slight increase in accordance with Stiasny's views as to the chemical nature of aldehyde-tannage (*loc. cit.*).—D. W.

Aldehyde tannage. W. Moeller. *Collegium*, 1920, 185—199. (See also J., 1920, 36 A.)

A REPLY to Gerngross (preceding abstract), in which the author affirms that the aldehyde combines with the hide decomposition products. The products of this reaction cannot tan the hide or render it insoluble in water, since they are readily soluble in water. The tanning agent consists of the insoluble polymers and condensation products formed from the excess of formaldehyde which form a protective covering round the fibres.—D. W.

Hydrolysis and adsorption; Relation between — [by hide powder]. I. W. Moeller. *Collegium*, 1920, 109—125, 152—166, 209—223, 267—276.

THE action of acids on hide powder is first one of hydrolysis, which proceeds much more quickly and strongly with inorganic than with organic acids. The presence of neutral salts appears to check the hydrolysis at first and then suddenly facilitates it. Besides the hydrolysis adsorption takes place between the non-hydrolysed protein micells, the products of hydrolysis, combined and uncombined with acid ions, and ionised and un-ionised protein molecules. The swelling is due to the increase in volume of the micellar strands caused by the adsorption of hydrated protein ions by the unattacked collagen micells in the hide substance. By the addition of neutral salts the hydrated hydrolysed collagen ions in the solution are dehydrated and no swelling can take place, although there may be subsequent adsorption. The effect of ampholytes on the hide powder is to restrict the hydrolysis. The apparent acidity of hide powder which has been in contact with acid for an hour and is then titrated in presence of different indicators differs from the actual acidity and forms no guide to the true conditions of the processes going on. With gelatin very different results are obtained owing to structural and chemical differences between gelatin and hide powder.—D. W.

Hydrolysis and adsorption; Relation between — [by hide powder]. II. W. Moeller. *Collegium*, 1920, 319—331, 382—387.

THE action of acids and alkalis on proteins, which is so frequently represented as being parallel to the adsorption process in dyeing and tanning, is quite different and cannot be cited as evidence for the chemical theory of tanning. The substances used in dyeing and tanning are either neutral or so feebly acid that hydrolytic effects on the animal fibres are either excluded or very much repressed.—D. W.

Nitrogen in leather; Rapid estimation of —. F. G. A. Enna. *Collegium*, 1920, 207—209.

One gm. of finely divided leather is heated with 8—10 g. of potassium sulphate and 20 c.c. of pure

concentrated sulphuric acid in a Kjeldahl flask over a large flame. After 10 mins. a small drop of mercury is added and the heating continued until the mixture becomes a very pale yellow. The flask is cooled, water added, followed by potassium sulphide and caustic soda solutions, and the ammonia is distilled into a saturated solution of boric acid. The determination can be completed in 2 hrs.—D. W.

Kjeldahl estimation of nitrogen [in leather]; Sources of error in the — and a modified method of expelling the ammonia. J. Kahn. *Collegium*, 1920, 367—371.

The chief sources of error are the irregularity of the ground leather sample, insufficient decomposition of the nitrogenous matter, the carrying over as spray of alkali, sodium sulphide, and even zinc particles in the ammonia distillation, and the escape of some of the ammonia which is unabsorbed. The modified method consists in fitting an Erlenmeyer flask with a dropping funnel containing the excess alkali protected from the air by means of a soda-lime tube fitted into the top of the funnel. A delivery tube from the flask leads to two wash bottles, one containing $N/1$ acid and the other water. The second bottle is attached to a filter pump. The solution for distillation is transferred to the Erlenmeyer flask which is placed in a water bath at $50^{\circ}C$. and gradually heated to boiling. Air is drawn through the apparatus for $1\frac{1}{2}$ —2 hrs. The alkali and sodium sulphide are gradually run in at the commencement from the dropping funnel.—D. W.

Free sulphuric acid in leather and animal hide; Determination and behaviour of —. C. Immerheiser. *Collegium*, 1920, 360—367.

A REPLY to Moeller's criticisms (J., 1919, 227 A). Leather treated with known amounts of sulphuric acid when analysed by the author's method has given an amount equal to that absorbed. The method is not influenced by any chlorides present. Experiments have shown the great reactivity of leather and hide for free acid, that of the latter being diminished by tanning in proportion to the acidity of the tanning agent employed. It is advisable to determine the nitrogen content of the aqueous extract of leathers under examination for harmful ingredients to determine whether the acid has decomposed the tissue.—D. W.

Gelatins and glues; Determination of the jellifying power of — by means of the polariscope. C. R. Smith. *J. Ind. Eng. Chem.*, 1920, 12, 878—881.

GELATINS of the highest jelly strength approximate to a definite and maximum value of mutarotation between 36° and $15^{\circ}C$. (cf. J., 1919, 228 A), and the polarimetric examination of gelatin in conjunction with certain other physical tests gives an indication of the relation of time, concentration, and temperature in the development of jelly strength. The smallest amounts to produce a standard jelly are required in the case of gelatins showing the greatest mutarotation at a concentration of 3 g. per 100 c.c.; as the mutarotation decreases, the amounts required to produce the standard jelly increase. For a gelatin which polarises $-20.5^{\circ}V$. at $35^{\circ}C$. and $-10.0^{\circ}V$. at $15^{\circ}C$., in a 200 mm. tube, it is suggested that the jelly strength be expressed as 19.5 points (i.e., the increment in rotation in Ventzke degrees); the maximum strength was found to be 25 points.—W. P. S.

XVI.—SOILS; FERTILISERS.

Fertiliser prepared by treating lime with end-liquors from potash works; Composition of —. J. Görbing. *Z. öffentl. Chem.*, 1920, 26, 205—213.

LIME fertilisers, prepared by sprinkling burned lime with potash end-liquors containing about 30% of magnesium chloride, are of complex composition, the assumption that they are merely mixtures of calcium hydroxide and magnesium chloride, with traces of magnesium hydroxide and calcium chloride, being erroneous. A sample examined consisted of a mass of damp, crumbly portions interspersed with hard lumps. An average sample had the following composition: Moisture (at $120^{\circ}C$), 30.41; CaO, 27.49; MgO, 11.37; K_2O , 0.58; Na_2O , 0.42; Fe_2O_3 and Al_2O_3 , 1.18; SiO_2 (sol.), 1.24; SiO_2 (insol.), 0.66; Cl, 11.87; CO_2 , 4.08; SO_3 , 1.76; P_2O_5 , Br. and organic impurities, traces; water of crystallisation and H_2O combined with lime and magnesium hydroxide (by difference), 7.83. A sample taken from the hard lumps gave: Moisture (at $120^{\circ}C$), 31.86; CaO, 36.63; MgO, 5.91; Cl, 4.89; CO_2 , 1.85. This sample gave a dry, non-hygroscopic powder which implies presence of oxychlorides. The decomposition of these in the soil is dependent on conditions of time, temperature, and concentration. A laboratory sample of the fertiliser treated with water on a filter gave a solution containing: CaO, 15.12; Cl, 11.75; K_2O , 0.60; Na_2O , 0.39; SiO_2 (sol.), 0.42; SO_3 , 1.39; with traces only of MgO, thus confirming the absence of magnesium chloride from the original material. The residue contained CaO, 12.4; MgO, 11.4%, and was of a light, pulverulent nature, and this condition was also produced with material exposed in the open for about six months, owing to atmospheric influences liberating the magnesia, which in the original material is present in a very finely divided condition and enclosed by calcium chloride. The liberated magnesia is in a very suitable form for distribution throughout the soil. Some photo-micrographs are appended.—W. J. W.

XVII.—SUGARS; STARCHES; GUMS.

Dextrose; Mutarotation of — in alkaline solution. H. Murschhauser. *Biochem. Zeits.*, 1920, 166, 23—36.

THE author has measured the rate at which the mutarotation of dextrose disappears in distilled water and in $N/10$ — $N/7000$ sodium carbonate solutions at $20.4^{\circ}C$. The values of the velocity constant of the change of mutarotation for different concentrations of sodium carbonate are: water, 7.11; $N/7000$, 7.32; $N/6000$, 9.32; $N/1500$, 12.70; $N/2000$, 24.4; $N/1000$, 56.5, and $N/500$, 93.1; these values give nearly a straight line when plotted against the concentrations of alkali.—T. H. P.

Maltose; Preparation of — [from starch]. M. Falch. Z. ges. Brauw., 1920, 43, 281—283, 289—291, 297—299, 306—309.

THE following method gives a yield of 30 pts. of pure maltose per 100 pts. of air-dry starch:—300 g. of potato starch is mixed with 1 l. of water and 30 c.c. of malt extract (made by digesting 1 pt. of pale kilned malt or green malt with 4 pts. of water for 3 hrs.), and the mixture is poured quickly into 2 l. of boiling water, with stirring, whereupon the starch is rapidly liquefied. After the temperature has fallen to 60° C., 30 c.c. of malt extract is added and the temperature is maintained for 2 hrs. after the liquid has ceased to react with iodine. The liquid is then heated to boiling, filtered, diluted to 7° Balling (sp. gr. 1.028), treated with 240 c.c. of malt extract, and with 7 mg. of hydrofluoric acid per 100 c.c., and maintained at 30° C. in a stoppered vessel for 3 days, during which no turbidity should appear. After addition of calcium carbonate the liquid is filtered, heated to boiling, evaporated to a water-content of 30%, preferably *in vacuo*, and then seeded with maltose crystals and maintained at 40° C. If crystallisation is very slow 3 separate quantities of 70 c.c. of 90% alcohol are added at intervals of 1 day. The crystals are collected with the aid of a pump, then mixed with 90% alcohol and again collected. 100 g. of the pressed product is dissolved in 30 c.c. of water on a water-bath, mixed with 260 c.c. of 90% alcohol, heated to boiling, and filtered. After cooling and seeding with maltose crystals, the liquid deposits pure maltose.—J. H. L.

PATENTS.

Sugar process. R. E. Pospisil and E. Kurek. U.S.P. 1,352,084, 7.9.20. Appl., 27.12.15.

WHITE granulated sugar is manufactured by treating raw juice to recover the first strike of sugar, boiling the syrup therefrom, together with a part of the dark sugar from a later massecuite, in a vacuum pan, subjecting the resulting sugar to water injections and raising the temperature to remove impurities, and re-melting the crystals and boiling to massecuite for white sugar.—J. H. L.

Explosives from carbohydrates. G.P. 298,949. See XXII.

XVIII.—FERMENTATION INDUSTRIES.

Fermentation in closed and open vats. E. Lühder. Z. Spiritusind., 1920, 43, 276, 283—284.

In distillery fermentations in large closed iron vats the temperature rises more rapidly during the early stages of fermentation and falls more rapidly during the later stages than in small open wooden vats. This difference cannot be altogether accounted for on physical grounds, e.g., loss of heat by conduction or surface exposure. Comparative fermentations of a filtered mash of rye and barley malt were carried out under identical conditions in similar, half-filled glass vessels, some of which were open and others closed by a stopper with glass tube and water seal. It was found that during the first 24 hrs. yeast reproduction (ascertained by counting cells) was almost twice as great in the closed as in the open vessels, e.g., 17-fold compared with 9-fold; but after 48 hrs. it was practically the same in both cases (18-fold compared with 17-fold), and no further change occurred afterwards. The yield of alcohol was the same in both cases, apart from a small loss by evaporation from the open vessels.—J. H. L.

Yeast; Rhythmic phenomena in the growth and fermentation of —. E. Köhler. Biochem. Zeits., 1920, 106, 194—206.

THE processes of fermentation and of yeast-growth are found to exhibit alternating maxima and minima of intensity; this periodicity appears to be due to alterations in the sugar and alcohol contents of the nutrient medium. The velocity with which yeast grows is conditioned by the concentration of the sugar and varies irregularly as the concentration increases.—T. H. P.

Alcoholic fermentation by yeast. E. Köhler. Biochem. Zeits., 1920, 108, 235—244.

THE course of alcoholic fermentation by yeast becomes rhythmic with increase in the concentration of the alcohol.—S. S. Z.

Methyl alcoholic fermentation; So-called —. E. O. von Lippmann. Biochem. Zeits., 1920, 106, 236—238.

OF 20 samples of genuine rums from the Lesser Antilles, 2 were found to contain from 1 to 2.5% of methyl alcohol, 7 from 2.5 to 5%, 5 from 5 to 7.5%, and 3 from 7.5 to 8.5%. In the district named the cane is largely pressed and the juice, being inadequately clarified, contains considerable proportions of very fine cane fibre, which passes to a large extent into the syrups and molasses. This fibre is rich in pectinous material and as the pectins consist of the methyl ester of pectinic acid, which is readily decomposed in various ways with liberation of methyl alcohol, the origin of the latter is evident.—T. H. P.

Maltose from starch. Falch. See XVII.

Enriching straw fodder. Pringsheim and Lichtenstein. See XIXA.

PATENTS.

Diastatic composition and process of making the same. J. Takamine. E.P. 131,579, 9.5.19. Conv., 20.8.18.

A DIASTATIC product is prepared by neutralising a diastatic extract, preferably with sodium bicarbonate, then adding a precipitant, such as magnesium or calcium chloride, and separating the precipitate. Claim is also made to a mixture of this precipitate with maize starch, sugar, and sodium phosphate, and to a process of bread making in which this mixture is employed without any further addition of sugar or malt extract and with less than the usual quantity of yeast.—J. H. L.

Acetone and butyl alcohol; Fermentation processes for production of —. C. Weizmann. E.P. 150,360, 25.5.17.

AMYLACEOUS materials of a nutty character, containing saponins, e.g., horse-chestnuts preferably freed from husk, are cooked under pressure, and the mash obtained is treated with malt and maintained at 60°—70° C. for some hours, after which it is cooled to 37° C. and fermented in accordance with E.P. 4845/15 and 9181/16 (J., 1919, 301A). The treatment with malt greatly reduces frothing during fermentation.—J. H. L.

Extracting alcohol from liquids; Process and apparatus for —. F. Fehr. U.S.P. 1,345,437, 6.7.20. Appl., 22.11.16.

THE liquid is heated in a closed tank to a temperature sufficient to volatilise the alcohol, without precipitating albuminoids or producing other changes in the character of the organic constituents of the liquid. An exhaust current is created from the upper end of the tank, so as to maintain a high vacuum and draw off the vola-

utilised alcohol, the upper end of the tank being heated to prevent premature condensation of the alcohol vapour. The liquid is circulated by drawing it off from the lower portion of the tank and discharging it in the form of spray into the upper portion above the body of the liquid. Air is drawn by the vacuum into the body of liquid in the tank, and into the circulating current of liquid prior to its encountering the spraying device, whereby a very fine spray is produced.—B. N.

XIXA.—FOODS.

Wheat; Nitrogenous substances and phosphoric acid in the ripening and germination of —. E. Rousseaux and Sirot. Comptes rend., 1920, 171, 578—580.

SAMPLES were examined taken from the time of the formation of grain on through harvest and from ears in the stook which had germinated owing to rain after the cutting. It was found that the total nitrogen and phosphoric acid of the grain vary little during this period. The proportion of the total nitrogen which is soluble diminishes rapidly, however, as the grain fills out and until the commencement of ripening, when it rises slightly and remains constant until the germination in the stook takes place. The same is practically true of the proportion of soluble phosphoric acid. During ripening the acidity of the grain diminishes steadily but increases again when the grain germinates.—W. G.

Wheat flour milling; Laboratory control of —. B. R. Jacobs and O. S. Rask. J. Ind. Eng. Chem., 1920, 12, 899—903.

THE inner endosperm, or true flour-producing portion of the wheat grain contains all the starch (the starch content is about 70% of the air-dried substance) and only very small quantities of fat (0.75%) and pentosans (2.25%); the bran tissue, including the aleurone layer, contains most of the pentosans, 5—6% of fat, and no starch, whilst the germ contains 12.5% of fat, no pentosans, and no starch. The pentosan content of offal tissue is fairly constant at 28.5%. The amount of fat and pentosans in a flour is, therefore, a measure of the amount of offal present; the percentage of starch is a measure of the quantity of inner endosperm or true flour in a sample.

—W. P. S.

Blood; Preservation of —. C. Oppenheimer. Biochem. Zeits., 1920, 105, 145—151.

BLOOD to be dried for use as human food has often to be kept for some time prior to drying. In order to prevent it from undergoing change it must be treated with a preservative which should, for convenience, either not require to be removed subsequently or be removed during the process of atomising the blood. For this purpose the author recommends the use of the following mixture, the quantities given being sufficient for all the blood of an ox, that is about 10 l.: 83 g. of commercial pure sodium sulphite (or about 40 g. of the anhydrous salt) is dissolved in 0.5—1 l. of water and the solution treated with about 52 c.c. of 38% hydrochloric acid, or 18.2 c.c. of concentrated sulphuric acid, or 49.3 g. of tartaric acid, or 41.4 g. of oxalic acid.

—T. H. P.

Straw fodder; Enrichment of — with the proteins of moulds. H. Pringsheim and S. Lichtenstein. Cellulosechemie, Beiblatt zu Papierfabr., 1920, 1, 29—39. Chem. Zentr., 1920, 91, IV., 414—415.

In experiments with a non-pathogenic *Aspergillus*

species it was found possible to use ammonium chloride and a mixture of kainite and superphosphate instead of ammonium sulphate and potassium phosphate in the nutrient solution. The solution is poured over the straw only once at the commencement, and subsequent daily turning of the couch is unnecessary. The depth of the couch should not exceed about 30 cm., in order to avoid undue rise of temperature, which should be kept below 40° C. Aeration of the resting couch with moist air appears very beneficial. Products containing 8% of protein can be obtained.—J. H. L.

Diastatic composition. E.P. 131,579. See XVIII.

XIXB.—WATER PURIFICATION; SANITATION.

Water softener; Data on operation of continuous type lime soda-ash —. R. F. Catherman and H. C. Fisher. Chem. and Met. Eng., 1920, 23, 526—528.

IT was found that the plant could be effectively controlled by testing the treated water at intervals and adjusting the addition of reagents from the results of the tests, the best figures for the hardness, causticity, and alkalinity having been determined by a series of preliminary tests.

—W. H. C.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids and their salts; Conductometric titration of —. I. M. Kolthoff. Z. anorg. Chem., 1920, 112, 196—208.

THE conductometric method of titration has been extended successfully to alkaloids and their salts in dilute solutions. For conductometric titrations of the alkaloid salts with alkali no alcohol need be used in most cases, but for acid titration of the alkaloid bases these are generally dissolved in 50% alcohol. The alkaloid salts tested included hydrochlorides of quinine, cocaine, tropacocaine, novocaine, morphine, and ethylmorphine, strychnine nitrate, and atropine sulphate. In the case of morphine hydrochloride no distinct break in the conductivity curve was found at the neutral point,

but since morphine has acidic properties, further titration with alkali gives a sharp break at the point where the formation of sodium morphinate is complete. For this titration 50% alcohol is used as solvent. The alkaloid bases examined included quinine, hydrastine, codeine, morphine, nicotine, theobromine, and caffeine. The last two have acidic properties, but since theobromine is a much stronger acid than caffeine, the former can be estimated in presence of the latter by dissolving the mixture in alkali and titrating with acid. The conductometric method may in certain cases be applied for the estimation of alkaloids in extracts, etc. Thus strychnine was successfully determined in a 10% extraction strychni solution.—E. H. R.

Tetranitromethane. II. Tetranitromethane as a nitrating agent. E. Schmidt and H. Fischer. Ber., 1920, 53, 1529—1537.

DECOMPOSITION of tetranitromethane into nitroform and nitric acid, which has been shown to occur almost exclusively, under the influence of very concentrated aqueous alkali, is found to take place in the presence of a weak base if solutions in acetone or alcohol are employed, the base becoming nitrated during the process and separating as its nitroform salt. Suitable non-basic substances can be similarly nitrated if the reaction is carried out in the presence of pyridine, when pyridine-nitroform is simultaneously produced. The process thus constitutes the first method of introducing the nitro-group into the aromatic nucleus in a non-acid medium. Its application to dimethyl-*p*-toluidine, diethyl-*p*-toluidine, dimethyl-*p*-anisidine, *p*-cresol, isosafrole, and anethole is described. (Cf. J.C.S., Nov.)—H. W.

Oxalic acid; Colour test for —. L. H. Chernoff. J. Amer. Chem. Soc., 1920, 42, 1784—1785.

A FEW crystals of resorcinol are dissolved in 5 c.c. of the solution by warming gently. The liquid is cooled and an equal volume of concentrated sulphuric acid slowly poured in to form a layer. A blue ring is formed at the junction of the layers if oxalic acid is present. If a blue colour does not appear the liquids are mixed by shaking and, after cooling somewhat, another 5 c.c. of sulphuric acid is added. If the colour still fails to appear the liquid is warmed over a flame (not boiled), when an indigo-blue colour appears. If the mixture is boiled the colour becomes dark-green. By warming the dry substance with 2 drops of a 10% resorcinol solution and adding sulphuric acid drop by drop, 1 mg. of oxalic acid can be detected.—J. R. P.

Aldehydes; Dehydrocoulation of —. Mechanism of oxidation. E. Müller. Annalen, 1920, 420, 241—261.

FORMALDEHYDE, acetaldehyde, and benzaldehyde are decomposed in alkaline solution either by electrochemical or purely chemical oxidation (by CuO , Cu_2O , Ag_2O) into acid and gaseous hydrogen. The latter is also evolved in small amount from alkaline solutions of formaldehyde in the presence of certain metals which also catalytically accelerate the Cannizzaro reaction. The primary product is considered to be an aldehyde peroxide. (Cf. J.C.S., Nov.)—H. W.

Ether apparatus and vagrant electric currents. O. Schaal. Chem.-Zeit., 1920, 44, 741.

To prevent the formation of electric currents and the consequent destruction of lead plant used in the manufacture of ether, all parts of the apparatus should be made of purest lead of the same quality and the plant connected with the earth in several places. Experiments have shown that weak currents (0.01 amp.) are generated in a mixture of sulphuric acid and alcohol by using hard lead as cathode and soft lead as anode.—C. A. M.

Phenols. Kolthoff. See III.

PATENTS.

Camphor; Recovery of — from gaseous mixtures. J. H. Bregeat. E.P. 150,651, 7.5.20.

GASES containing camphor, e.g., from the manufacture of celluloid etc., are passed through scrubbers moistened by a counter current of an absorbent consisting of phenol or its homologues, especially cresols. The camphor may subsequently be separated from the phenolic absorbent by the direct action of steam or by indirect heating, or by dissolving the phenols in alkali, in which case the phenols may be recovered for further use by acidification, preferably with an acid salt. (Cf. E.P. 127,309, 128,640, and 131,938; J., 1919, 521 A, 612 A, 751 A.)—J. H. L.

Acetaldehyde; [Apparatus for use in the] production of —. M. Soller and J. L. R. Hotz. E.P. 151,086, 14.6.19.

THE lead linings of the vessels used in the process described in E.P. 105,061 (J., 1918, 222 A) are protected from amalgamation with mercury by electrolytically coating the surface with a layer of lead peroxide. The vessel itself, filled with 5—10% sulphuric acid, is used as the anode, and a sheet of lead serves as cathode. A current of 100 amps. and 5 volts is passed through for about 10 hrs., and, after washing and drying the layer of lead peroxide, the process is repeated.—L. A. C.

Ethylidene diacetate; Manufacture of —. M. Beudet, Assr. to Soc. Chim. des Usines du Rhône, anc. Gilliard, P. Monnet et Cartier. U.S.P. 1,351,990, 7.9.20. Appl., 22.3.19.

CRUDE ethylidene diacetate, obtained by the action of acetylene on acetic acid in presence of mercury compounds, is decanted and diluted, and the resulting solution is agitated with an immiscible solvent of ethylidene diacetate; the latter is recovered by washing, drying, and distilling the extract.

—J. H. L.

Tropine; Homologue of — and process of producing same. E. Müller, Assr. to Hoffmann-La Roche Chemical Works. U.S.P. 1,352,082, 7.9.20. Appl., 16.12.16.

A HOMOLOGUE of tropine is produced by the action of sodium on dihydroanhydroecgonine alkyl ester dissolved in absolute alcohol. It is readily soluble in ether, benzene, alcohol, and water, slightly soluble in petroleum ether, crystallises from ligroin in long needles, m.p. 85° C., is dextrorotatory, and yields a hydrochloride, m.p. 210° C., soluble in water and alcohol and insoluble in ether, and a platinum compound and picrate slightly soluble in water.—J. H. L.

Tannate-lime compound difficultly soluble in dilute acids; Process for producing —. R. Tambach, Assr. to Chemical Foundation, Inc. U.S.P. 1,352,768, 14.9.20. Appl., 10.3.17.

Explosives from carbohydrates; Production of —. Harburger Chem. Werke Schön und Co., and W. Daitz. G.P. 298,949, 9.3.16.

A SOLUTION of carbohydrates (sugar, starch, cellulose) is saturated with hydrogen with the aid of a catalyst, and after the removal of the latter the product is nitrated. The catalyst is prepared by treating a solution of nickel sulphate with an excess of magnesia. An alkaline reaction accelerates hydrogenation.—J. H. L.

Explosive which can be detonated by mercury fulminate and containing no nitric acid residue; Production of —. J. D. Riedel A.-G. G.P. 301,799, 24.12.14.

KIESELGUHR or similar material is impregnated with alkylchloramines, e.g., methylchloramine.—J. H. L.

Signal lights and fire balls; Manufacture of — free from metals and shellac. Geka-Werke Offenbach G. Krebs. G.P. 322,779, 24.3.18. Addn. to 314,868 (J.), 1920, 430 A).

STRONTIUM carbonate and potassium chlorate or perchlorate are used instead of strontium nitrate and barium peroxide, and the organic solvent is replaced by water, which evaporates on drying so that the binding of the materials depends solely on the softening of the pitch.—J. H. L.

XXIII.—ANALYSIS.

Phosphoric acid and its salts; Conductometric titration of —. I. M. Kolthoff. Z. anorg. Chem., 1920, 112, 165—171.

PHOSPHORIC acid, in common with other strong acids, cannot be titrated conductometrically in concentrated solution. In dilute solution it can be titrated in exactly the same way as mono- or dibasic acids. The first break in the curve, corresponding with primary salt formation, is sharp, the second less distinct, and the third very uncertain owing to the hydrolysis of tertiary phosphates. The conductometric method is superior to the indicator method for titrating dilute solutions of phosphoric acid, but, for more concentrated solutions, indicators are to be preferred. Secondary phosphates, e.g., Na_2HPO_4 , can be titrated conductometrically with acid when the concentration is less than 0.01 molar, but with greater concentration the break in the curve corresponding with NaH_2PO_4 is indistinct owing to the dissociation of phosphoric acid. Dilute solutions of tertiary pyrophosphates can be titrated satisfactorily with acid to the secondary salt.—E. H. R.

Ammonia; Determination of — in urine, in serous liquids, and in the oxidised liquid of the Kjeldahl method. A. Hahn and E. Kootz. Biochem. Zeits., 1920, 105, 220—228.

WITH Hahn's modification of the Krüger, Reich, and Schittenhelm method, all the ammonia is expelled in 5 min. from a solution containing 0.01 g. of ammonia as ammonium sulphate, 25 c.c. of water, 10 g. of sodium chloride, 1 g. of sodium carbonate, and 30 c.c. of 96% alcohol, if the distillation flask is heated in a boiling-water bath and the distillation is carried out in the maximum vacuum given by a water pump. Under these conditions urea (2 g.) yields no ammonia. Cooling of the receiver con-

taining the standard acid for absorbing the ammonia is unnecessary. Methods based on the above results are given for the determination of ammonia in albumin-free urine, albuminous urine, and blood serum.—T. H. P.

Carbonic acid and its salts; Conductometric determination of —. I. M. Kolthoff. Z. anorg. Chem., 1920, 112, 155—161.

SOLUTIONS of carbonic acid from 0.0015 to 0.02 molar in strength can be titrated conductometrically with alkali. The breaks in the curve, corresponding with bicarbonate and carbonate formation, are not very sharp, but their sharpness can be considerably increased by titrating in presence of a calcium salt, e.g., calcium chloride. Time must be allowed during the titration for the calcium carbonate to be precipitated. Carbonate solutions can be satisfactorily titrated with acids. The bicarbonate break in the conductivity curve is not sharp, but the neutral point is very sharp, even in extremely dilute solutions. Alkali can be determined in presence of carbonate by acid titration, whilst bicarbonate in carbonate can be titrated with acid or alkali. To obtain accurate results, however, the proportion of alkali or bicarbonate in the carbonate must not be too small, or the direction of the corresponding portion of the conductivity curve cannot be accurately determined. (Cf. J.C.S., Nov.)—E. H. R.

Tin; Volumetric determination of —. J. G. F. Druce. Chem. News, 1920, 121, 173—175.

TIN may be accurately determined by titrating stannous solutions with standard iodine solution in the presence of hydrochloric acid. Good results are also obtained by titration with potassium permanganate in the presence of sulphuric acid. (Cf. J.C.S., Nov.)—C. A. M.

PATENT.

Hardness of metal parts; Ascertaining the —. E. Schneider. Assr. to Schneider et Cie. U.S.P. (A, B, C) 1,351,216—8, 28.9.20. Appl. (A) 21.8.18, (B, C) 16.6.19. (B, 4) Renewed 12.8.20.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

British Thomson-Houston Co. (General Electric Co.). Removing gases from solids. 29,309. Oct. 16.

Comp. Gén. d'Electricité. 29,075. *See* X.
Conover. Apparatus for bringing about reactions between gases. 29,641. Oct. 20. (U.S., 30,419.)

Duckham, and Woodall, Duckham, and Jones. Furnaces for producing chemical changes. 29,194 and 30,059. Oct. 14 and 23.

Duckham, Morgan, and Thermal Industrial and Chemical Research Co. Heating materials at successively different temperatures. 29,678. Oct. 20.

Fischer. Pyrogenic reactions. 29,911. Oct. 22. (Ger., 22.10.19.)

Foster. Apparatus for cleaning gases. 29,275. Oct. 16.

Koppers Co. Purification of liquids. 29,013. Oct. 13. (U.S., 15.2.19.)

Morgan, and Thermal Industrial and Chemical Research Co. Evaporation of liquids. 29,677. Oct. 20.

Norsk Hydro-Elektrisk Kvaelfstafaktieselskab. Impregnation of liquids. 30,052. Oct. 23. (Norway, 24.11.19.)

Pyzel. Distillation. 29,525. Oct. 19.

Soc. des Gaz Radioactifs Naturels de Colombières sur Orb. Cooling liquids and charging same with gas. 29,815. Oct. 21. (Fr., 22.10.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

13,137 (1918). Windram. Separating crystals from mother liquors containing more than one salt. (152,041.) Oct. 20.

2482 (1919). Lewis and Green. Distilling or recovering volatile inflammable liquids or solvents. (152,374.) Oct. 27.

17,113 (1919). Hall. Ball or tube mills. (152,398.) Oct. 27.

18,584 (1919). Reol. *See* X.

24,048 (1919). Imray (Secord, Peters, and Paterson). Drying apparatus. (152,505.) Oct. 27.

31,371 (1919). Norske Akt. for Elektrokemisk Industri. Manufacture of porous material. (136,818.) Oct. 20.

32,433 (1919). Henning. Solvents for extraction purposes. (152,550.) Oct. 27.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Asiatic Petroleum Co., and Cameron. Dehydrating emulsions and/or distilling oils etc. 29,821. Oct. 21.

Bamber and Parker. Gas-producers etc. 29,647. Oct. 20.

Bartolomeis, and Colombo & Ing. de Bartolomeis. Distillation of fuels. 29,365. Oct. 8. (Ital., 18.10.19.)

Coke Oven Construction Co., and Marr. Coke ovens. 29,412. Oct. 18.

Comerford. Fuel. 29,329. Oct. 18.

Davis and Twigg. Producer-gas plant. 29,557. Oct. 19.

Docking, and Sharp and Preston. Rotary retort furnaces. 30,011. Oct. 23.

Fabry. Regenerative coke ovens. 29,748. Oct. 21.

Farbenfabr. vorm. F. Bayer u. Co. 29,215. *See* VII.

Fischer. 29,911. *See* I.

Fonblanque and Moeller. Manufacture of illuminating gas and by-products. 29,250. Oct. 16.

Fonblanque and Moeller. Treatment of peat. 29,253. Oct. 16.

Foster. Gas for power purposes. 29,459. Oct. 19.

Gibson. Coal-saving composition. 28,958. Oct. 13.

Glover, West, and West's Gas Improvement Co. Vertical retorts for destructive distillation of carbonaceous material. 29,307. Oct. 16.

Hart. Production of carbon. 29,119. Oct. 14.

McEwen, and Underfeed Stoker Co. Carbonisation of subdivided fuel. 28,778. Oct. 11.

Marks (U.S. Industrial Alcohol Co.) Non-freezing fuel. 28,995. Oct. 13.

Strache. Combustion of bituminous fuels with recovery of by-products. 29,551. Oct. 19. (Austria, 6.8.19.)

Worthington. Utilising peat or turf for heating and for generating steam, electricity, or gas. 29,701. Oct. 21.

COMPLETE SPECIFICATIONS ACCEPTED.

1166 (1918). Litwin. Gas-producer furnaces for heating gas retorts. (152,369.) Oct. 27.

12,278 (1919). Dille. Suction gas plants. (152,380.) Oct. 27.

17,547 (1919). Roberts. Recovery of by-products of the destructive distillation of wood in suction gas plants. (152,420.) Oct. 27.

17,810 (1919). Wallace. Apparatus for recovering oil from shale or other carbonaceous materials. (129,996.) Oct. 20.

17,811 (1919). Wallace. Distilling carbonaceous materials. (129,997.) Oct. 20.

24,906 (1919). Long. Manufacture of fuel from peat. (152,515.) Oct. 27.

26,013 (1919). Siemens u. Co. Electric light carbons. (134,225.) Oct. 27.

30,379 (1919). Grisard. Neutralising mineral oils which have been treated with acid. (136,169.) Oct. 27.

32,220 (1919). Woodall, Duckham, and Jones, and Gardner. Vertical retorts for carbonising coal. (152,548.) Oct. 27.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Atack. 28,692. *See* XX.

Johnson (Badische Anilin u. Soda Fabr.). Production of soluble condensation products. 28,749. Oct. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

10,918 (1919). Stephenson. Dealing with acid sludge produced in purifying benzol, and recovering benzol and its homologues. (152,054.) Oct. 20.

17,849 (1919). Morgan, and British Dyestuffs Corp. Manufacture of 4-nitro- β -naphthol. (152,437.) Oct. 27.

20,217 (1919). South Metropolitan Gas Co., Evans, and Hollings. Purification of benzole or the like. (152,470.) Oct. 27.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Cassella und Co., and Herz. Manufacture of dyestuffs. 29,096. Oct. 14.

Johnson (Badische Anilin u. Soda Fabr.). Manufacture of anthraquinone derivatives. 29,517. Oct. 19.

COMPLETE SPECIFICATION ACCEPTED.

3557 (1914). Newton (Bayer u. Co.). Manufacture of azo dyestuffs. Oct. 20.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

British Cellulose and Chemical Manuf. Co., and Palmer. Manufacture of textile products from cellulose derivatives. 29,629. Oct. 20.

British Cellulose and Chemical Manuf. Co., and Shuttleworth. Treatment of artificial threads. 29,630-1. Oct. 20.

Chadwick and Chadwick. Preparatory treatment of cotton etc. 29,873. Oct. 22.

Clotworthy. Treatment of artificial filaments or threads and fabrics containing same. 29,630. Oct. 20.

Edmunds. Treatment of jute waste. 29,751. Oct. 21.

Glanzfüden A.-G. Producing spun material resembling wool or cotton from viscose solutions. 28,982-1. Oct. 13. (Ger., 27.3, 6.4, and 15.8.18.)

Sandeman. Treatment of jute etc. 30,041. Oct. 23.

Tootall Broadhurst Lee Co., and Willows. Treatment of yarn and fabrics of cotton etc. 29,039. Oct. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

24,788 (1919). Poole and Davis. Washing or scouring wool. (152,513.) Oct. 27.

706 (1920). Great Northern Paper Co. Method and machine for making paper. (137,539.) Oct. 27.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Blanc and Jourdan. Treating potassic rocks etc. to obtain constituents in soluble form. 29,235. Oct. 15.

Craig. Recovering potash etc. salts from blast furnace gases. 29,710. Oct. 21.

Davis and Levy. Generation of oxygen. 29,671. Oct. 20.

Farbenfabr. vorm. F. Bayer u. Co. Obtaining sulphur or treating and purifying gases containing hydrogen sulphide. 29,215. Oct. 15. (Ger., 30.10.19.)

Foster. Producing oxygen and agricultural lime. 29,029—29,030. Oct. 13.

Johnson (Badische Anilin u. Soda Fabr.). Extraction of sulphur. 28,895. Oct. 12.

Mathieson Alkali Works. Production of barium chloride. 29,882. Oct. 22. (U.S., 22.1.20.)

Schott u. Gen. Rendering boronatrocalcite soluble. 28,723. Oct. 11. (Ger., 24.10.19.)

Soc. l'Air Liquide. Catalytic materials for synthesis of ammonia. 29,850. Oct. 21. (Fr., 28.10.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

11,955 (1917). Wade (Deuts. Gold- u. Silber-Scheide-Anstalt). Manufacture of alkali percarbonates. (152,366.) Oct. 27.

15,045 (1919). Richards and Hutchinson. Recovery of soluble nitrogen compounds from solutions. (152,387.) Oct. 27.

17,246 (1919). Ashcroft. Production of anhydrous magnesium chloride or anhydrous double chlorides of magnesium. (152,401.) Oct. 27.

17,247 (1919). Ashcroft. Electrolytic decomposition of anhydrous magnesium chloride and production of magnesium and chlorine. (152,402.) Oct. 27.

18,255 (1919). Collins. Separating sulphur from gases obtained in roasting and smelting sulphur-bearing ores. (152,447.) Oct. 27.

26,317 (1919). Uchino. Refining arsenious acid. (152,526.) Oct. 27.

366 (1920). Toniolo, and Officine Elettrochimiche Dr. Rossi. Production of hydrogen. (152,554.) Oct. 27.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Bailey. Kilns for firing pottery etc. 29,700. Oct. 21.

Friedrich. 29,370. See X.

COMPLETE SPECIFICATION ACCEPTED.

24,383 (1919). Priest. See X.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Curtis. Cementitious compositions for flooring, paving, etc. 28,952. Oct. 13.

Jager. Production of artificial marble. 29,077. Oct. 14. (Holland, 14.10.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

16,817 (1919). Lesley. Utilising low-grade carboniferous material in the manufacture of Portland cement. (152,106.) Oct. 20.

17,638 (1919). Slade. Colouring wood grey or black. (152,427.) Oct. 27.

23,277 (1920). Boverouille. Manufacture of cement from slag. (149,988.) Oct. 20.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Abraham and Thain. Separating minerals etc. 29,475. Oct. 19.

Bengough. Coating metals with lead. 29,953. Oct. 22.

British Thomson-Houston Co. (General Electric Co.). Melting pots. 29,633. Oct. 20.

Comp. Gén. d'Electricité. Pot or crucible furnaces. 29,075. Oct. 14. (Fr., 20.10.19.)

Craig. 29,710. See VII.

Electrolytic Zinc Co. Treatment of finely-divided zinc. 30,057. Oct. 23. (Australia, 24.10.19.)

Friedrich. Production of glaze-like mineral coatings for iron. 29,370. Oct. 18. (Ger., 18.10.19.)

Hall, and Rolls-Royce Ltd. Aluminium-bronze alloys. 29,673. Oct. 20.

Johnston. Apparatus for separating metals from ores. 30,026. Oct. 23.

Lockwood. Treating ores, concentrates, tailings, etc. 29,214. Oct. 15.

Morton (Gibson). Alloys. 29,200. Oct. 15.

Rheinisch-Nassauische Bergwerks u. Hütten A.-G. Rotary roasting and calcining furnaces. 29,532. Oct. 19. (Ger., 20.10.19.)

Richards. Manufacture of steel. 29,679. Oct. 20.

Vickers, Ltd., and Wilson. Anti-corrosive composition. 29,550. Oct. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

9268 (1918). British Thomson-Houston Co. (General Electric Co.). Manufacture of steel. (152,371.) Oct. 27.

20,840 (1918). Rossi. Production of an acid-proof alloy. (121,730.) Oct. 20.

16,514 (1919). Rouse. Extraction of iron and steel from ore and formation of alloys thereof. (152,073.) Oct. 20.

17,190 and 20,201 (1919). Ballantine. Production of chrome iron or chrome steel alloys. (152,399.) Oct. 27.

17,247 (1919). Ashcroft. See VII.

17,248 (1919). Ashcroft. Production of magnesium or its alloys. (152,403.) Oct. 27.

18,255 (1919). Collins. See VII.

18,584 (1919). Reol. Apparatus for dehydrating, reducing, calcining, or roasting minerals or other pulverulent material. (130,978.) Oct. 27.

19,262 (1919). Dudzele et Cie. Coating articles with metal. (139,143.) Oct. 27.

22,057 (1919). Ansell. Combined flux solder for aluminium. (152,486.) Oct. 27.

24,383 (1919). Priest. Continuous regenerative gas-fired kilns for burning ore-briquettes and high-temperature refractory materials. (152,509.) Oct. 27.

4975 (1920). Gerber. Manufacture of aluminium. (139,194.) Oct. 27.
 10,125 (1920). Bangerter. Alloy. (152,277.) Oct. 20.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Mond (Internat. Precipitation Co.). Electrical precipitation of suspended particles from gaseous media. 29,185. Oct. 15.
 Selvatico. Manufacture of electric furnaces and ovens. 29,640. Oct. 20.
 Smalley. Electric furnaces. 29,780. Oct. 21. (U.S., 21,10,19.)

COMPLETE SPECIFICATIONS ACCEPTED.

9489 (1919). Lodge, Lodge, and Lodge Fume Deposit Co. Electrical deposition of particles from gases. (152,051.) Oct. 20.
 17,247 (1919). Ashcroft. *See* VII.
 18,016 (1919). Electro-Metals, Ltd., and Robertson. Electric furnaces. (152,145.) Oct. 20.
 19,571 (1919). British Thomson-Houston Co. (General Electric Co.). Electric induction furnaces. (152,157.) Oct. 20.
 21,342 (1919). Heyen. Electric arc furnaces. (152,176.) Oct. 20.
 24,813 (1919). Soc. Anon. des Ateliers de Secheron. Electric resistance heaters and furnaces for high temperatures. (133,706.) Oct. 27.
 28,743 (1919). Soc. Anon. des Ateliers de Secheron. Electric furnaces. (138,858.) Oct. 27.
 28,744 and 30,520 (1919). Soc. Anon. des Ateliers de Secheron. Electric resistance heaters and furnaces. (138,859 and 137,276.) Oct. 27.

XII.—FATS; OILS; WAXES.

COMPLETE SPECIFICATIONS ACCEPTED.

16,741 and 20,192 (1919). Howse. Nitration of oils or fatty acids. (152,095.) Oct. 20.
 19,901 (1919). Morel. Manufacture of soap. (131,881.) Oct. 27.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Frood. Production and utilisation of phenol-aldehyde condensation products. 28,929. Oct. 13.
 Vickers, Ltd., and Wilson. 29,550. *See* X.

COMPLETE SPECIFICATION ACCEPTED.

14,694 (1919). Weller and Bindley. Phenol-formaldehyde condensation products and the production thereof. (152,384.) Oct. 27.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Campbell and Pheazey. 29,501. *See* XV.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Adachi and Nakayama. Utilisation of leather waste. 28,712. Oct. 11.
 Campbell and Pheazey. Manufacture of artificial leather and substitutes for rubber, gutta-percha, etc. 29,501. Oct. 19.
 Jacobsen. Impregnating and greasing leathers. 28,912. Oct. 12.
 Röhm. Depilating, neutralising, and bating hides and skins. 28,904. Oct. 12. (Ger., 31,12,19.)

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Alby United Carbide Factories, and Dodd. Manufacture of fertilisers containing nitrogen and phosphate. 29,090. Oct. 14.
 Foster. 29,029 and 29,030. *See* VII.
 Messerschmitt. Manufacture of manures. 29,969. Oct. 22.

XVII.—SUGARS; STARCHES; GUMS.

COMPLETE SPECIFICATION ACCEPTED.

1976 (1920). Verein. Chem. Werke. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Dixen and Moore. Manufacture of yeast, ales, stout, etc. 28,695. Oct. 11.

COMPLETE SPECIFICATION ACCEPTED.

1976 (1920). Verein. Chem. Werke. Manufacture of glycerol from sugar. (138,330.) Oct. 27.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Candy. Apparatus for purifying water. 28,927. Oct. 13.
 Candy. Apparatus for proportionate addition of liquid to flowing water. 29,078. Oct. 14.
 Chaviara, Clayton, and Nodder. Manufacture of margarine etc. 28,951. Oct. 13.
 Solomides. Insecticides and fungicides. 29,410. Oct. 18.
 Thomson. Alcoholic solution of animal etc. proteins for human use. 30,048. Oct. 23.

COMPLETE SPECIFICATION ACCEPTED.

20,134 (1919). Beckmann, and Veredelungsges. f. Nahrungs- u. Futtermittel. Manufacture of fodder from straw. (151,229.) Oct. 20.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Atack. Oxidation of hydrocarbons having side chains. 28,692. Oct. 11.
 Imray (Meister, Lucius, u. Brüning). Manufacture of therapeutically active acridine compounds. 29,106. Oct. 14.
 Wacker Ges. f. Elektro Chem. Ind. Manufacture of dichloroethylene. 29,956. Oct. 22. (Ger., 23,12,19.)

COMPLETE SPECIFICATION ACCEPTED.

22,739 (1919). Damiens, Loisy, and Piette. Manufacture of alcohol or ether. (152,495.) Oct. 27.

XXII.—EXPLOSIVES; MATCHES.

COMPLETE SPECIFICATION ACCEPTED.

24,120 (1919). Muller. Manufacture of ammonium nitrate explosives. (152,199.) Oct. 20.

XXIII.—ANALYSIS.

APPLICATION.

Hilger, Ltd., Smith, and Williams. Polarimeters of polarimeters, saccharimeters, etc. 29,333. Oct. 18.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Pulverising apparatus. J. Aube. E.P. 151,072, 12.6.19.

Is an apparatus employing air or other gas for separating the ground material, the fan and dust separator are external to the grinding mill, the gas circulating in a closed circuit. A rotating gas distributor is keyed to the central driving shaft of the mill and distributes the inlet air, and the outlets for air and dust are controlled by dampers.

—B. M. V.

Pulverisers. A. E. Davis. E.P. 151,440, 16.8.19.

Is pulverisers for coal and similar materials, the ground material is drawn by suction from the beater chamber through a vertical screen arranged in a chamber above and of the same width as the beater chamber. Baffles are provided to prevent large pieces being flung directly from the beater blades on to the screen, but permitting the oversize material to drop back directly into the beater chamber. Means are provided for rapid removal of the screen for cleaning or repairs.—B. M. V.

Rotary machines for treating air or gases with liquid, and vice versa. W. J. Bulgin, E. A. Hall, and G. Searle. E.P. 151,314, 21.5.19.

The effective surface of a rotary machine for the treatment of air or gas with liquid, and vice versa, is constituted of helically twisted or corrugated metal strip, expanded metal, or metallic wool wound in layers, carried by a cylindrical support, through the surface of which the air or gas to be treated passes substantially radially. The cylindrical support rotates about a horizontal axis within a casing, so that the effective surface just dips into liquid contained in the lower part of the casing. Alternatively, the liquid may be supplied by pipes to the effective surface.—J. S. G. T.

Furnaces [; Recuperative —]. A. Smallwood. E.P. 151,366, 24.6.19.

Is the type of furnace where a working chamber, gas chamber, and recuperator are arranged one above the other, the heated air is led up flues on each side of the furnace to ports in the working chamber which, together with the adjacent gas ports, are individually controlled by dampers; the waste gases leave the furnace at one end and pass to the recuperator.—B. M. V.

Furnaces [; Recuperative gas —]. A. Smallwood. E.P. 151,367, 24.6.19.

Is a furnace of the type in which recuperators are arranged under the working chamber, the waste gases are withdrawn through outlets disposed along the sides of the working chamber, while the gas and heated air are admitted through ports in the floor of the chamber from their appropriate flues underneath.—B. M. V.

Heat exchange devices. Maison F. Fouché. E.P. 151,551, 20.3.20. Conv., 12.2.20.

A HEAT exchanger, more particularly applicable to steam condensers and coolers for liquids and gases, comprises a number of juxtaposed or superposed radiator elements each composed of a coil of high-pressure tubing having a connecting sleeve at each end. These sleeves are hollow and comprise an inner and outer wall, and stepped end walls which fit tightly against each other. The sleeves slide along a collector tube in which there is a longitudinal slot, and are clamped in position by a nut or other device. Distance rings can be inserted

between two sleeves and are provided with joint faces corresponding to those of the sleeves.

—J. S. G. T.

Heat-insulating material for steam and other pipes, boilers, cylinders, and the like; Manufacture of —. J. D. Gilmour. E.P. 151,738, 3.7.19.

THE waste products, consisting mainly of calcium carbonate, obtained in the manufacture of caustic soda and sodium hypochlorite, and in the leaching of bleaching powder, are mixed with 10% of fibrous material (preferably asbestos) and with water to the consistency of stiff mortar. The mixture is cast into moulds, transferred from the mould to a flanged semi-cylindrical core, and dried in an oven. Before mixing with the fibrous substance the waste materials may be treated with carbon dioxide from waste chimney gases to convert any calcium hydroxide into flocculent calcium carbonate. If asbestos is not used, a veneer of waste material with asbestos is applied, so that the latter only is in contact with the heated surface.—H. S. H.

Mixer. J. Johnson. U.S.P. 1,353,165, 21.9.20. Appl., 21.2.19.

A ROTARY mixer is mounted on a vertical shaft and arranged at the bottom of a vessel containing the material to be mixed. Material is directed outwards through the mixer by centrifugal force, circulates upwards through the vessel at the periphery, and then downwards at the centre to the central opening of the mixer. Means are arranged at the inlet of the mixer to impose on the incoming material a movement radially inwards.—W. F. F.

Dissolver; Rapid —. J. Johnson. U.S.P. 1,353,166, 21.9.20. Appl., 21.2.19.

A CONTAINER has pockets at the bottom formed by radial partitions extending inwards about half the radius of the container, and the material to be dissolved is placed in these pockets. A central rotating wheel and guide blades are arranged to direct the solvent liquid into the pockets.—W. F. F.

Dehydrator. W. M. Luther. U.S.P. 1,353,167, 21.9.20. Appl., 26.9.19.

A CASING contains a series of L-shaped heating pipes attached at one end to a transverse inlet header, and at the other end to a longitudinal outlet header. A reducing valve is placed in the inlet pipe. Superposed horizontal conveyors are arranged so that the uppermost projects through one end of the casing and the lowermost through the other end. A spreader is arranged at the inlet of the uppermost conveyor, and the material passes from each conveyor to the next below. The conveyors are driven through variable speed gearing, and travel alternately in opposite directions with a wave-like motion.—W. F. F.

Drying or cooling apparatus. P. Steinfeldt-Lindholm. U.S.P. 1,353,358, 21.9.20. Appl., 11.3.19.

THE material to be dried is supported on shelves arranged to form a zig-zag channel for the passage of air heated to the desired temperature. The air is heated in a passage located on one side of and below the drying chamber, and after passing over the material is led through a chamber above the drying chamber, containing hygroscopic material.

—J. S. G. T.

Dryer. F. C. M. Yahn, Assr. to Buffalo Foundry and Machine Co. U.S.P. 1,353,980, 28.9.20. Appl., 27.1.19.

THE material is dried on a moving surface, from which it is scraped and falls off between plates which form the walls of a jacket through which a cooling fluid is passed.—B. M. V.

Leaching machine. G. S. Dyer. U.S.P. 1,353,463, 21.9.20. Appl., 27.8.19.

MATERIAL to be treated is fed at one end into a rotary cylindrical leaching chamber. A longitudinal series of transverse annular partitions divides the chamber into compartments, and diametrically opposite shifter plates, spaced at their outer edges from the partitions and extending at their inner edges through central openings in the partitions, are arranged adjacent to each partition and oblique thereto. A pipe for supplying water is provided at the other end of the chamber. Each compartment of the chamber can be supplied independently with steam through a pipe placed outside the peripheries of the openings in the partitions. At the end of the chamber at which water is supplied, the steam pipes are jacketed by a washing chamber.
—J. S. G. T.

Catalytic reactions in the vapour phase; Producing —. F. A. Canon, Assr. to The Barrett Co. U.S.P. 1,355,105, 5.10.20. Appl., 18.4.19.

A CIRCULATORY motion is imparted to a catalyst suspended in a gas mixture.—L. A. C.

Atomising liquids, or solids dissolved or suspended in them; Process for —. H. Seiferheld. G.P. 302,554, 20.2.17.

ATOMISING of liquids may be promoted by dissolving a gas in the liquid and so raising its vapour tension considerably. Solids may be atomised by dissolving them in a liquid and then treating this as above. In the application of the method to atomising water for use in sulphuric acid chambers, or for washing gases in the contact process, sulphur dioxide is dissolved in the water. The process is applicable to alcohols, ether, olefines, and mineral acids and to naphthalene, camphor, pinacones, and phenol, and, in addition to sulphur dioxide, carbon dioxide and monoxide, nitrogen oxides, or air may be employed.—W. J. W.

Gases; Process for cooling — previous to liquefaction. Chem. Fabr. Griesheim-Elektron. G.P. 324,266, 16.2.17.

THE dry waste gas leaving the apparatus is cooled by saturation with a cooling liquid, and is then used to cool the gas to be liquefied.—L. A. C.

Dryers; Rotary —. O. Imray. From W. J. Kuntz. E.P. 151,518, 31.12.19.

SEE U.S.P. 1,229,978 of 1917; J., 1917, 918.

II A—FUEL; GAS; MINERAL OILS AND WAXES.

Benzene formed in gas retorts and coke ovens; Origin of —. F. Fischer and H. Schrader. Brennstoff-Chem., 1920, 1, 4-6, 22-24.

PREVIOUS theories on the formation of benzene are shown to be untenable. It is shown experimentally that phenols when heated with hydrogen yield benzene, $C_6H_5(CH_3)OH + H_2 = C_6H_6 + CH_3 + H_2O$, and $C_6H_5CH_3 + H_2 = C_6H_6 + CH_4$, and this reaction may be of importance in the manufacture of benzene from tar. With iron tubes only poor yields of benzene were obtained and much carbon separated, but with tinned iron tubes, at 750° C., good yields (up to 78%) were obtained from phenols and from toluene and higher benzene homologues. Hexane yielded very little benzene, but high yields were obtained from diphenyl, aniline, diphenylmethane, and diphenylamine.—J. R. P.

Methane; Behaviour of — at high temperatures alone and in contact with the other constituents in firedamp explosions. H. Winter. Brennstoff-Chem., 1920, 1, 17-22.

IN mixtures of pure methane and air containing 5.0-9.2% CH_4 combustion takes place according to the equation $CH_4 + 2O_2 = CO_2 + 2H_2O$. In mixtures containing 9.2-14% CH_4 combustion of the methane is incomplete. In addition to carbon dioxide, water, and hydrogen, the residues contain carbon monoxide when the ratio $O_2:CH_4$ is somewhat greater than, equal to, or less than 2.0:1. When the concentration of oxygen becomes smaller, hydrogen appears in addition to carbon dioxide and monoxide, nitrogen, and water. The explosion under these conditions is also accompanied by deposition of carbon within a small area.—J. R. P.

Gasoline from natural gas. IV. Temperature correction and blending charts. R. P. Anderson. J. Ind. Eng. Chem., 1920, 12, 1011-1015.

A NOMOGRAPHIC chart based upon the relationship between the coefficient of expansion and the sp. gr. of gasoline is given; also temperature correction tables for Baumé gravity and volume extending from 30° F. to -20° F.; and a blending chart for blending two grades of gasoline, or gasoline and naphtha.—C. A. M.

Petroleum distillates; Use of alcohol in refining —. Z. Budrewicz. Przemysł Chem., 1920, 4, 63-64. Chem. Zentr., 1920, 91, IV., 448.

IN the refining of Baku solar oil with sulphuric acid, alcohol is added in some factories to remove the sulphonic acids, aqueous solutions of which form persistent emulsions with mineral oils. The oil, after treatment with sulphuric acid, is warmed to 50° C., treated with 0.25-0.3% of alcohol, shaken

for 1 hr., and allowed to stand. The sulphonic acids are then run off and the oil is washed. In this way 7% of sulphonic acids have been produced from Baku solar oil. They possess detergent and emulsifying properties in acid, neutral, and alkaline solutions and in hard waters.—J. H. L.

Paraffin wax; Influence of high temperatures on — H. Burstyn and W. Jakubowicz. *Przemysł Chem.*, 1919, 3, 36—42. *Chem. Zentr.*, 1920, 91, IV., 448—449.

Crude petroleum from Boryslaw, sp. gr. 0.856, after treatment with 50% of 98% sulphuric acid at 40° C. and subsequent washing, was distilled. According as the distillation was stopped at 150°, 200°, 250°, or 300° C., the proportion of paraffin wax obtained from the residue was 13.8%, 12.8%, 12.2%, or 10.1%. In each case the paraffin had a setting point of 51–59° C. Since no appreciable amount of paraffin wax passed into the distillates the differences in the amount of wax obtained are attributed to decomposition, which is stated to occur even at 125° C., mainly owing to the action of the air. On this account distillation *in vacuo* is recommended.

—J. H. L.

Ozokerite; Determination of paraffin wax in — A. S. Koss. *Przemysł Chem.*, 1920, 4, 74—76. *Chem. Zentr.*, 1920, 91, IV., 449—450.

From 2 to 5 g. of the paraffin distillate is mixed with 20% of animal charcoal previously dried at 140° C., and the mixture is extracted with petrol of b.p. 50°–60° C. The extract, containing the total paraffin wax and the paraffin oil, is freed from petrol, dissolved in warm acetone, and cooled to –22° C., whereupon the paraffin wax crystallises whilst the oil remains in solution. After filtering and washing with acetone at –22° C., the paraffin is dried at 100° C. The soft paraffins separate from the acetone solution only at –30° C. A sample of ozokerite showed 47.35% of paraffin by the Engler-Höfer method, and 65.85% by the method described above.—J. H. L.

Mineral oil products; Determination of the iodine value of — W. R. Röderer. *Z. angew. Chem.*, 1920, 33, 235—237.

The Hübl-Waller and Wijs iodine solutions are the most suitable for lignite tars and distillates. With the former the maximum values are obtained in 24 hrs. with a 5-fold excess of iodine, and with the latter in 16 hrs. with a 10-fold excess. Crude petroleum oils require a double excess of iodine with Wijs' solution and a period of 16 hrs., and montan wax a 10-fold excess. In the case of each product it is necessary to determine the effect of iodine excess and of time.—C. A. M.

Oil emulsions; New technical methods for separating aqueous — I. Maseicki and K. Kling. *Przemysł Chem.*, 1920, 4, 2—8. *Chem. Zentr.*, 1920, 91, IV., 448.

In accordance with the method previously suggested (J., 1919, 885A), aqueous mineral oil emulsions may be separated by maintaining them for 2–4 hrs. at 120°–140° C. under 2–6 atm. pressure in a perfectly air-tight pressure vessel. The emulsion may be forced continuously under pressure through a preheating system into a vertical holder, in which it slowly rises. The dimensions of the holder are such that the emulsion remains in it for several hours at a temperature high enough to effect separation. The separated oil is discharged through a pressure valve at the top of the holder, and the separated water is discharged from the bottom.—J. H. L.

Gelatin as an emulsifying agent [for kerosene]. H. N. Holmes and W. C. Child. *J. Amer. Chem. Soc.*, 1920, 42, 2049—2056.

In the emulsification of kerosene in water and salt

solutions by the aid of gelatin the maximum lowering of the surface tension should be obtained. This is secured just as well by 0.3–0.4 g. of gelatin per 100 c.c. of water as by 1.0 g. Acids, bases, and liquefying salts (sodium iodide, chloride, and nitrate) also lower it a little, whilst solidifying salts (sodium sulphate, tartrate, and citrate) raise it. Viscosity must not be increased more than a little beyond that of water. A small amount of gelatin only may therefore be used or the gelatin must be liquefied by suitable electrolytes. The latter method yields the better emulsion. An excess of acid, base, or liquefying salt must not be used. The main factor in oil-water emulsification with the aid of gelatin is viscosity—not the maximum but the most favourable viscosity. (Cf. J.C.S., Dec.)

PATENTS.

Burning fuel. H. H. Hurt, Assr. to Robeson Process Co. U.S.P. 1,329,300, 27.1.20. Appl., 11.5.18.

FINELY divided fuel is wetted down with concentrated sulphite-cellulose waste lye and charged on to a fire bed.

Retorts for distilling carbonaceous materials. J. West, W. Wild, and West's Gas Improvement Co. E.P. 144,051, 7.5.19.

A SET of horizontal or inclined gas retorts discharge into a vertical chamber, heated externally, into which steam is injected to produce water-gas by interaction with the coke from the retorts. The water-gas passes through the retorts and mixes with the distillation gases. The vertical chamber may be discharged continuously or intermittently. The retorts are heated by products of combustion from chambers below, the gases, after passing back and forth across the retorts, being led down the opposite sides of the vertical coke chamber. The retorts are supported on walls which serve as baffles to equalise the heating.

Coke-oven and like gases; Recovery of ammonia from — Soc. Ind. de Prod. Chim. E.P. 136,834, 27.9.18. Conv., 27.5.18.

THE ammonia is absorbed in a solution of sodium bisulphate at 70° C. The precipitate of sodium-ammonium sulphate which forms is separated, dried, and heated, first at 100° C. to expel water of crystallisation, and then at 350°–600° C. to decompose it into ammonia and sodium bisulphate.

Gas producers. J. F. Wells. E.P. 141,520, 1.9.19.

AROUND the producer chamber is an annular water space through which tuyères extend to deliver air to the producer. The air is supplied by an injector, which may be operated by the exhaust of the engine or, before the injector comes into operation, by an auxiliary fan. The air may first be drawn over the surface of the water in the annular space to become charged with steam, or the annular space may be closed and the steam generated used to actuate the injector. The ashes are discharged by a screw conveyor working in a chamber below the producer.

Suction gas generators. J. Franklin. E.P. 151,329, 18.6.19.

A CYLINDRICAL generator is provided with a fire-brick lining, 12, surrounded by asbestos, 13, supported on the firebar supports, 8, and extending upwards to a level short of the bottom of the feed hopper, 9. The generator is surrounded by an annular space, 16, packed with wire netting, 27, and a pipe, 18, is provided connecting the upper

end of this space with the ashpit, 14. Gas is drawn from the generator through the pipe, 33, to the cooler and washer, 34, and thence to the main,

35. In operation the damper, 19, is closed and 20 opened, and the cover, 10, removed, so that air is drawn through the pipe, 21, and upwards through the fire. The damper, 19, is then opened and 20 closed, water is admitted to the channel, 24, and the cover, 10, replaced. Air and steam are thus drawn through the packing, 27, and ashpit, 14, to the fire to generate water-gas. The water supply is regulated automatically by the suction pressure of the engine, which acts upon the piston, 47.

—W. F. F.

Gas producer. F. J. Grocott. E.P. 151,520, 15.1.20.

A gas producer mounted on a truck is provided with a vertical partition extending downwards from the top for about half the height. A fuel supply hopper is arranged at the top of one of the compartments and a gas outlet at the top of the other. Another gas outlet at the side of the latter compartment is connected with a furnace where the gas is to be used as fuel. The gas flows to the outlet at the top as soon as it is opened, and hence connexion of the other outlet with the furnace is facilitated.—W. F. F.

Gas mixtures; Removal of carbon monoxide from — S. Fränkel. G.P. 303,931, 7.3.16.

In the use of chromic acid, in presence of sulphuric acid, as a gas absorption agent, the addition of catalysts is prescribed, suitable materials being mercuric oxide, silver oxide, palladium oxide, and oxides and compounds of metals such as iron, manganese, chromium, and tungsten, which combine with oxygen in various proportions.—W. J. W.

Gas cleaning apparatus. J. F. Wells. E.P. 151,443, 20.8.19.

An apparatus for cleaning gas and extracting tar is built up of separate elements mounted on a horizontal shaft, the number of elements being variable. The casing is divided into transverse compartments by annular partitions clamped between circumferential rings, and paddles are arranged to rotate in the compartments. Each paddle is provided with a central disc so that the gas is compelled to take a tortuous path alternately outwards and inwards over the paddles and through the central openings in the partitions. A propelling fan is provided in the end compartment and tar outlets at the bottom of each compartment.—W. F. F.

Naphthalene from gas obtained by the distillation of coal; Apparatus for the complete extraction of — D. Marbais and C. Deguido. E.P. 151,463, 13.9.19.

Coal gas containing naphthalene is passed through

a refrigerator, where it is cooled to 18° C., and then upwards through a scrubber in counter-current to anthracene oil which is sprayed into the top at 22° C. The anthracene oil may be mixed with about 4% of benzol to prevent absorption of benzol from the gas. The oil is subsequently distilled with steam to free it from naphthalene, and is then passed through a cooler supplied with cold water from the gas cooler first mentioned, where it is cooled to 22° C. and supplied again to the scrubber. (Cf. E.P. 118,730; J., 1918, 616 A.)—W. F. F.

Ammonia; Preparation of — from gas liquor. G. Schuchardt. G.P. 324,582, 16.7.19.

In the process in which the ammonia is driven off by means of hot air, both the air and liquor feeds are preheated by the heat of the retorts.—C. I.

[Petroleum] hydrocarbons; Apparatus for cracking — J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,353,316, 21.9.20. Appl., 27.9.17.

The oil is circulated through two cracking elements, one a pipe, and the other a relatively large still. The pressure is regulated in the still by an outlet valve, and in the pipe by a valve in one of the connexions between the two elements. Vapour passes out of the still into a condenser.—L. A. C.

Gasoline and other products; Apparatus for producing — from hydrocarbons. A. A. Daugherty. U.S.P. 1,353,638, 21.9.20. Appl., 23.5.17.

HYDROCARBON oils are heated above 700° F. (370° C.) and under a pressure of more than 300 lb. per sq. in., and are allowed to expand suddenly to atmospheric pressure. The expansion vessel is heated to vaporise any condensed liquid, and the vapour is withdrawn therefrom by suction and passed into a condenser.—L. A. C.

Hydrocarbons; Continuous production of light — from heavy hydrocarbons and waste products thereof by distillation under pressure. Zeller und Gmelin. G.P. 303,235, 29.10.15.

The oil is first subjected to a cracking process under a low excess pressure to remove substances which are liable to form coke and pitch, and then subjected to a continuous distillation process under a high pressure in an autoclave.—J. H. L.

Oils; Process and apparatus for separating — from mixtures by means of continuous distillation and concentration columns. Maschinenbau-A.-G. Golzern-Grimma. G.P. 324,280, 20.2.18.

THE residue leaving the concentrator passes into a reservoir heated by the distillation column, and either returns as vapour to the concentrator, or overflows into the distillation column.—L. A. C.

Lubricant; Production of a consistent — from mineral oil and resin oil. Dr. Graf und Co., and A. Fischer. G.P. 323,905, 12.2.18. Conv., 4.2.18.

An aqueous emulsion consisting of resin oil or distillation residues therefrom, mineral oil, and aqueous ammonia, is intimately mixed with milk of lime and then treated with an aqueous solution of aluminium or zinc sulphate. The greater part of the water is then separated, preferably by means of a filter-press, and the residue is intimately mixed with mineral oil and, if desired, with an aniline dye. On heating for several hours, the product undergoes a reaction, with elimination of water, and a lubricant very stable towards heat is produced which is suitable for high-speed engines, automobiles, etc.—J. H. L.

Coke; Manufacture of — and apparatus therefor. F. J. Sivyer. U.S.P. 1,354,809, 5.10.20. Appl., 15.11.17.

PATENTS.

Metallic-filament electric lamps; Removing film from [bulb of] used —. F. Harrison. U.S.P. 1,353,654, 21.9.20. Appl., 8.7.19.

THE inner surface of the bulb is washed with hydrogen peroxide.—J. S. G. T.

Electrical discharge tubes. Siemens und Halske A.-G. G.P. 323,205, 11.3.13.

IN discharge tubes conductivity is caused by nitrogen obtained by the use of electrodes of a metal such as tantalum, which absorbs large volumes of the gas and again evolves it on heating.—W. J. W.

Electrodes for discharge tubes; Manufacture of — from light metals. Studien-Ges. für elektrische Leuchtröhren m.b.H. G.P. 323,494, 3.11.17.

COMPOUNDS of the desired metals which are readily decomposed, or mixtures of these, are decomposed in the discharge tubes or in vessels in connection with them. Suitable compounds are metallic azides or a mixture of sodium azide and barium chloride.—W. J. W.

Products from carbohydrates. U.S.P. 1,327,737—8. See XI.

III.—TAR AND TAR PRODUCTS.

Aromatic compounds; Use of catalysts in the sulphonation of —. J. A. Ambler and W. J. Cotton. J. Ind. Eng. Chem., 1920, 12, 968—969.

BENZENE was dissolved in 70% sulphuric acid and sulphonated at 243° to 259° C. in the presence of various catalysts (0.1% of the active element of the weight of sulphuric acid). Compounds of copper, mercury, vanadium, chromium, potassium, and lithium had a slight catalytic action, whilst mixtures of sodium sulphate and vanadium pentoxide were the most active. The increased sulphonation caused by the presence of sodium and potassium sulphates in the sulphonation mixtures was not entirely due to the increase in the boiling point of the sulphuric acid. The formation of disulphonic acid was promoted by the presence of sodium or lithium sulphate, and still more so by the mixture of vanadium pentoxide and sodium sulphate, but was inhibited by the other catalysts.—C. A. M.

Formation of benzene. Fischer and Schrader. See IIA.

Iodine value of mineral oils. Röderer. See IIA.

PATENTS.

Anthranol; Manufacture of —. A. G. Perkin. E.P. 151,707, 26.6.19.

ANTHRANOL is obtained by heating anthraquinone (60 pts.) with glucose (60 pts.) and a 30% solution of sodium hydroxide (650 pts.) in an autoclave provided with stirring gear at 230° C. for 5—10 hrs. The anthranol is precipitated from the reaction mixture by the addition of hydrochloric acid or by leading in carbon dioxide. Instead of glucose, sucrose, molasses, maltose, lactose, and the like may be used with similar results.—G. F. M.

Anthracene; Catalytic oxidation of —. J. M. Weiss and C. R. Downs, Assrs. to The Barrett Co. U.S.P. 1,355,098, 5.10.20. Appl., 1.11.18.

ANTHRACENE vapour is treated with oxygen in the presence of a vanadium oxide at 300°—500° C.—L. A. C.

Coal-tar product; Process of making a —. J. M. Weiss, Assr. to The Barrett Co. U.S.P. 1,355,099, 5.10.20. Appl., 27.10.19.

THE constituents of tar bitumen soluble in coal-tar naphtha are treated with petroleum naphtha, and the soluble portion is separated from the residue.—L. A. C.

Coal-tar distillates; Treatment of high-boiling — for the production of resinous products. G. C. Bailey and F. Boettner, Assrs. to The Barrett Co. U.S.P. 1,355,103, 5.10.20. Appl., 27.10.19.

A HARD, transparent, red resin, m.p. above 40° C., which does not darken on exposure to air and light, is prepared by extracting a high-boiling solid to semi-solid coal-tar bitumen with a solvent, filtering the solution, and, after separation of the solvent by distillation, purifying the product by fractional distillation *in vacuo*.—L. A. C.

Chlorobenzoyl-benzoic acid; Production of —. J. M. Weiss, G. C. Bailey, and R. S. Potter, Assrs. to The Barrett Co. U.S.P. 1,355,100, 5.10.20. Appl., 12.12.19.

As a step in the production of chlorobenzoyl-benzoic acid, a mixture of phthalic anhydride and aluminium chloride, from which all particles small enough to pass through a 20-mesh sieve have been removed, is added to chlorobenzene at a temperature above 110° C.—L. A. C.

Hydronaphthalenes; Production of —. Tetralin Ges.m.b.H. G.P. (A) 299,012, and (n) 299,013, 2.8.16.

(A) VAPORISED naphthalene is brought into intimate contact with finely-divided or easily fusible metals, alloys, or feeble non-saline compounds of such metals, either with or without the additional presence of finely-divided or porous materials such as fuller's earth; after this process of purification, which occurs more rapidly in the gaseous than in the liquid state, the material is reduced with hydrogen and a catalyst. Sodium or finely-divided iron and nickel are suitable for the preliminary purification; the subsequent reduction with a nickel catalyst can be effected at 100° C. (n) Instead of vaporised naphthalene, a solution in a suitable organic solvent, such as tetrahydronaphthalene, may be used for the purification process.—D. F. T.

Naphthalene; Hydrogenation of —. K. Wimmer. G.P. 300,052, 14.3.15.

THE hydrogenation catalyst is obtained by heating an organic salt, such as nickel formate, in a saturated glyceride with hydrogen. The product permits the reduction of naphthalene at 180° C., by hydrogen under a pressure of 15 atm., to deca-

hydronaphthalene. A mixture of the hydronaphthalenes with benzene or petroleum spirit can be used as motor fuel.—D. F. T.

Chlorinated derivatives of naphthalene of waxy consistency; Production of —. Chem. Fabr. Griesheim-Elektron. G.P. 322,794, 10.12.18. Addn. to 319,253 (J., 1920, 442 A).

In the process described in the original patent, the chlorination may be checked when the product has a solidifying point of 110°–118° C., after which air or an inert gas is blown through it at 200° C. The chlorine-content of the product may reach 58%.—W. J. W.

Benzol refining; Still for recovery of sulphuric acid used in —. O. Schröder. G.P. 324,731, 16.9.19.

The still can be tipped, and a removable lid carries the steam jet and vapour exit pipe.—C. I.

Distilling oils. G.P. 324,280. See IIa.

Artificial resin. U.S.P. 1,353,220. See XIII.

Oil varnish substitute. G.P. 323,155. See XIII.

Fatty acids etc. G.P. 324,663. See XX.

IV.—COLOURING MATTERS AND DYES.

PATENTS.

Colours soluble in fats and oils and process of preparing the same. W. Clark. From Chem. Fabr. Worms A.-G. E.P. 151,657, 8.5.18.

COLOURS suitable for printing or for colouring resinous and fatty materials are prepared by treating the colour bases of basic dyes with a naphthenic or montanic acid, or by treating alizarin dyes with an alkali salt of a naphthenic or montanic acid and with aluminium sulphate.—L. A. C.

Diphenylamine derivatives [dyestuffs]; Manufacture of —. British Dyestuffs Corp., Ltd., J. Turner, and L. G. Badier. E.P. 151,868, 17.12.19.

New dyestuffs are obtained by bringing into reaction with alkali cyanides the ammonium or sodium salts of a nitrated diphenylamine derivative which yields water-soluble alkali salts, such as hexanitrodiphenylamine, tetranitrothio-oxydiphenylamine, or the sulphonic acids of dinitrodiphenylamine. The products are precipitated from the reaction mixture by the addition of common salt. They produce, on wool, brown to purple shades, fast to light.—G. F. M.

Dye-soap; Process of manufacture of —. C. S. Robison, Assr. to Aladdin Products Co. U.S.P. 1,353,182, 21.9.20. Appl., 25.10.17.

A MIXTURE of coconut oil (10 pts.), castor oil (10 pts.), and tallow (8 pts.) is saponified at 50° C. with 14 pts. of sodium hydroxide solution (38° B., sp. gr. 1.357), a solution of 8 pts. of granulated sugar in 8½ pts. of water at 85° C. is added, the mixture is neutralised with coconut oil and fatty acid, and an alcoholic solution of a dye is mixed with the soap solution at 60° C.—L. A. C.

Dyes of the Magenta type; Process of producing —. J. L. Kane. U.S.P. 1,355,048, 5.10.20. Appl., 21.12.19.

As a step in the production of alkyltriarylamine dyes, a salt of an alkyltriarylamine is produced by the interaction of an aromatic amine, an aromatic nitro compound, and an acid in the presence of a starchy material.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Reeds (Arundo phragmites L.); Utilisation of —. E. Heuser. Papierfabr., 1920, 115. Chem.-Zeit., 1920, 44, Rep., 236.

THE cellulose content of the root stems of the common reed (*Arundo phragmites*) was determined by Cross and Bevan's chlorination method. The cellulose obtained contained 1.09% of ash and 24.74% of pentosan. The chlorination method gives therefore not the percentage of pure cellulose, but of crude cellulose. Calculated to an air-dried and ash-free basis the following figures were obtained:—25.42% pure cellulose, 44.02% lignin, 14.78% pentosan, 10.68% moisture. By fermentation of the aqueous extract two experiments gave an average yield of 9.28 l. of alcohol from 100 kg. of dry substance. A similar plant, the reed mace (*Typha latifolia*), was worked up in Germany during the war to hemicellulose for cattle food. This hemicellulose had the composition 58.70% pure cellulose, 28.05% pentosan, 9.45% lignin, and 3.80% ash.—G. F. M.

PATENTS.

Spanish moss; Method of utilizing —. M. W. Marsden. U.S.P. 1,327,873, 13.1.20. Appl., 18.7.18.

THE material is boiled with dilute sulphuric acid, and the liquid is separated and used for production of sugar, alcohol, etc. The cellular residue is suitable for conversion into nitrocellulose, artificial silk, etc.; or after boiling with a solution of soap and glycerin, washing, and drying, may be used as a filling for mattresses etc.

[Pile] fabrics; Colloid-treated — and method of producing the same. S. P. Lovell. U.S.P. 1,353,599, 21.9.20. Appl., 16.1.20.

VILLOUS pile fabric, impregnated with a solution of colloidal matter, is passed through a pile-opening mechanism and thence through a precipitating bath, whereby a colloidal material, insoluble in water, is deposited between the fibres of the pile.

—A. J. H.

Cellulose fibre; Method of producing —. J. A. de Cew. U.S.P. 1,354,731, 5.10.20. Appl., 21.10.19.

LIGNOCELLULOSE is impregnated with a solution containing 15% of caustic soda under the usual conditions of temperature and pressure of pulp cooking. Excess of alkali is then removed so that the lignone is attacked only by the alkali absorbed.

—A. J. H.

Broom; Production of textile fibres from —. A. Hammer. G.P. 323,607, 22.3.18.

THE plants are boiled, preferably under pressure, in a sodium hydroxide solution of about 5° B. (sp. gr. 1.036) until the cortex is disintegrated and can be removed by washing; the fibres freed from cortex are separated from the woody stems by combing with hackles of graded fineness.—J. H. L.

Straw and similar materials; Production of textile fibres from —. G. Strauss. G.P. 323,669, 21.9.19.

STRAW is steeped for a long time in a mixture of aqueous ammonia, sodium hydroxide, and tanning material.—J. H. L.

Cellulose acetates; Process for the manufacture of —. H. A. Levey. U.S.P. 1,330,543, 10.2.20. Appl., 13.7.18.

CELLULOSE is treated with chlorinated acetic acid, i.e., glacial acetic acid which has been treated with chlorine until it is distinctly yellow, and when dis-

integrated the excess acid is expressed and the mass dissolved in a mixture of acetic acid and zinc chloride at 55°–70° C. and further treated with chlorinated acetic acid for 12–36 hrs., at 50°–70° C. The product is then washed and dried at 60°–75° C. It is soluble in ethyl acetate, ethyl butyrate, and pyridine, and insoluble in benzene, carbon tetrachloride, and alcohol.

Cellulose-nitrate composition, and process of making the same. Mixed cellulose-ester composition, and process of making the same. S. J. Carroll, Assr. to Eastman Kodak Co. U.S.P. (a) 1,351,725 and (n) 1,351,726, 5.10.20. Appl., 2.1.20.

A COLLOIDAL mixture of tetrachloronaphthalene and triphenyl phosphato is combined with a solution containing (a) nitrocellulose and fusel oil, or (n) nitrocellulose, cellulose acetate, and fusel oil.

—A. J. H.

Cellulose; Production of (A) soda — from vegetable materials of all kinds, (n) pure soda-celluloses from wood, straw, esparto, rushes, bamboo, manila and other vegetable materials by double digestion with alkalis and acids. M. Müller. G.P. (a) 323,743, 18.6.19, and (n) 323,744, 21.8.19.

(A) DIGESTION is effected by means of soda or sulphate solutions to which alkali or alkaline-earth salts of lower fatty acids have been added or in which such salts have been formed by addition of lower fatty acids. Crude calcium acetate which contains calcium phenolate has a very favourable influence, and the addition of tar oils assists digestion. (n) Soda-cellulose produced by known methods of alkaline or neutral digestion is further treated with mixtures of inorganic and organic acids or their salts. The mother liquors from this second treatment contain precipitable substances which can be used for loading and sizing paper, etc.

J. H. L.

Cellulosic materials; Digestion of wood and other — with the aid of chlorine. A. Franz. G.P. 323,936, 18.9.19.

THE chlorine is used dissolved in an indifferent solvent, such as carbon tetrachloride. After extraction of the product with a 2% aqueous sodium hydroxide solution pure cellulose is obtained.

—J. H. L.

Sulphite-waste-liquor preparation and process of making the same. F. E. Coombs. U.S.P. 1,327,862, 13.1.20. Appl., 12.9.19.

SULPHITE-cellulose waste liquor is reduced with iron and acid and then concentrated, or the liquor is first concentrated and then reduced. The product, after dilution, may be used for dyeing unmordanted wool greenish-brown, and is also useful as an insecticide and for dressing the surface of roads.

Sizing of paper, cardboard, textile fabrics, etc., by means of sulphite-cellulose waste liquors. E. Rasch. G.P. 323,627, 31.5.16.

CONCENTRATED waste liquors are used without removal of the bases present, and if necessary with addition of further bases. If the calcium compounds present in the liquors are decomposed and the lime removed, the adhesive properties are impaired.—J. H. L.

Cellulose acetate; Manufacture of compositions, preparations, or articles having a basis of —. H. Dreyfus. U.S.P. 1,353,384–5, 21.9.20. Appl., 15.4.19.

SEE E.P. 132,283 and 133,353 of 1918; J., 1919, 896A; 1920, 14A.

Paper-making machines and the like [; Arrangement of suction boxes in —]. J. Heess and R. J. Marx. E.P. 151,516, 15.12.19.

Burning fuel. U.S.P. 1,329,300. See IIA.

Aluminium compounds for sizing. G.P. 323,626. See VII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Discharging Indigo Blue with glucose; Methods for —. A. Scheunert and N. Wosnessensky. Sealed notes 1990, 6.4.10; 1991, 22.4.10; 2019, 20.7.10; and 2075, 15.3.11. Bull. Soc. Ind. Mulhouse, 1920, 86, 263–266. Report by M. Battegay, *ibid.*, 266–267.

WHITE discharge effects are obtained by printing a fabric dyed with Indigo Blue, with a paste containing 300 g. of glucose, 700 g. of thickening, and (optional) 100 g. of zinc oxide and 50 g. of Leucotrope W, passing it through a solution of caustic soda of 30° B. (sp. gr. 1.26) at 100°–110° C., and immediately through boiling water. A short steaming of the fabric previous to treatment with caustic soda improves the result. For coloured effects the discharge paste contains 250 pts. of a suitable dye, 300 pts. of glucose and 450 pts. of thickening. The process may be combined with the production of ingrain dyes, the discharge paste then containing 200 g. of glucose, 150 g. of a solution of diazotised α -naphthylamine, chloroaniline, or benzidine, 50 g. of Leucotrope W, and 600 g. of thickening, and being used on indigo-dyed cloth prepared with β -naphthol. A brilliant red discharge is obtained by use of a paste containing 250 g. of a solution of diazotised Azo Rose BBI, 200 g. of glucose, 500 g. of British gum, and 50 g. of Leucotrope W. The printed material is passed through a caustic soda bath at 100° C. If 50 g. of stannous chloride be added to the above discharge pastes, the quantity of glucose used may be reduced by one-half, the caustic soda solution may be at 20°–25° B. (sp. gr. 1.16–1.21) and the resulting colours are more brilliant and intense. Battegay reports that the processes are better than the usual one in which the discharge paste consists of a mixture of glucose and caustic soda.—A. J. H.

Discharges on tannin-antimony mordanted cotton; Production of white and coloured —. J. Pokorny. Sealed note 2063, 25.1.11. Bull. Soc. Ind. Mulhouse, 1920, 86, 260–261. Report by P. Binder, *ibid.*, 261–262.

COTTON fabric mordanted with antimony tannate is printed with a thickened solution of a vat dye-stuff, overprinted with a discharge paste containing caustic soda, steamed in a Mather-Platt, washed, soaped, and dyed with basic dyes. The caustic soda simultaneously fixes the vat dye and destroys the mordant. Improved effects are obtained by incorporating glucose with the mordant, by chroming after steaming, and by adding about 50 g. of an alcoholic solution of β -naphthol to the vat dyestuff. Binder reports favourably on the process, which has been previously suggested for discharges on indigo. The temperature should not exceed 30°–50° C. whilst after-chroming, in order to avoid dulling the coloured ground.—A. J. H.

Reserves under Indanthrene Blue; Process for printing —. J. Pokorny. Sealed notes 2180–1 and 2186–7, 23.5 and 26.6.12. Bull. Soc. Ind. Mulhouse, 1920, 86, 257–258. Report by P. Binder, *ibid.*, 258–259.

COTTON fabric is printed with a reserve paste containing manganous chloride without the addition of a bichromate, dried, and dyed with Indanthrene Blue. A suitable paste for white reserves consists of 370 pts. of manganous chloride, 550 pts. of gum tragacanth, and 80 pts. of water. For red reserves

on cloth prepared with β -naphthol the paste contains 293 pts. of manganous chloride, 509 pts. of gum tragacanth, 165 pts. of a solution of diazotised *p*-nitro-*o*-anisidine, and 33 pts. of sodium acetate. A paste suitable for yellow reserves consists of 240 pts. of manganous chloride, 200 pts. of Indanthrene Yellow R. paste, 500 pts. of gum tragacanth, and 60 pts. of water. The addition of 150 pts. of stannous chloride to 1000 pts. of one of the above pastes, allows reserves under Indanthrene Blue and overprinted azo dyes to be obtained simultaneously. Binder reports that the process works well.

—A. J. H.

PATENTS.

Dye jig rollers. W. Dean and T. Lyttle. E.P. 152,285, 19.6.20.

Dye-soap. U.S.P. 1,353,182. See IV.

Sulphite-waste-liquor preparation. U.S.P. 1,327,862. See V.

Washing and cleaning. G.P. 323,193. See XII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Method of recovering — from sodium bisulphate. I. Moscicki and W. Dominik. *Przemysl Chem.*, 1920, 4, 17—23. *Chem. Zentr.*, 1920, 91, IV., 430.

Sodium bisulphate is mixed with an equal quantity of sand or sodium sulphate, and the sulphuric acid is then distilled off, only about 0.1% H_2SO_4 remaining in the residue.—W. J. W.

Nitric acid; Fractionation of —. J. Baumann. *Chem.-Zeit.*, 1920, 44, 678.

By distilling 69.8% nitric acid (sp. gr. 1.4) using a dephlegmator heated to 100° C., equal volumes of distillate containing 0.02% of HNO_3 and of residue containing 69.5% were obtained. Distillation of 500 c.c. 91.5% acid using a dephlegmator heated at 86° C. yielded 140 c.c. of 70.1% acid (the constant boiling mixture), and a residue of 350 c.c. of 100.5% acid.

Chlorine; Preparation of — from hydrochloric acid or chlorides. J. Baumann. *Chem.-Zeit.*, 1920, 44, 677.

The whole of the chlorine in hydrochloric acid or chlorides can be liberated by means of nitric acid of about 52% strength, and the nitric acid recovered unchanged, if the chlorine compound is added slowly to the boiling acid, using a long dephlegmator, and passing a current of air into the reacting gases. (*Cf.* J.C.S., ii., 684.)

Ammonia; Very high pressures and the synthesis of —. G. Claude. *Bull. Soc. Chim.*, 1920, 27, 705—724.

The author gives an historical account of the developments in the synthesis of ammonia, and a description of the application of pressures up to 1000 atm. to this process. (*Cf.* J., 1919, 885A; 1920, 61A, 187A, 655A.)—W. G.

Ammoniacal liquor; Automatic supply of steam in distillation of —. G. Frère. *Soc. Techn. du Gaz.* Gas J., 1920, 150, 841—842.

The lower part of the boiler from which steam is supplied to the still is connected with a reservoir open at the top; the level of the water in the reservoir hence varies with the steam pressure. A pipe with its lower end cut at an angle extends into the reservoir so that its end is partly sealed by the water. This pipe is connected with a pipe leading to the

boiler furnace, and according to the steam pressure and hence the water level in the reservoir, the end of the first pipe is more or less uncovered and more or less air passes through to the furnace. A similar device may be used when the steam supply comes from an independent source, but in this case the reservoir is provided with a counterbalanced float which actuates a valve on the steam supply pipe.

Carbon dioxide; Determination of — in bicarbonates in the presence of carbonates. W. Hartmann. *Z. anal. Chem.*, 1920, 59, 289—297.

In a mixture of alkali bicarbonate and carbonate, the former may be decomposed completely by heating the mixture with 70% glycerin at 114°—117° C. for 10 mins., and the evolved carbon dioxide may be collected and weighed. At the end of the 10 mins., the temperature should be lowered to 100° C., and a current of air aspirated through the apparatus to carry over all the carbon dioxide into the potash bulb. The alkali carbonate present is not affected by this treatment, but the carbon dioxide in this salt may be determined in the same way by heating the residue at 180°—190° C. for 5 mins., then adding 2 drops of water, continuing the heating for 10 mins., cooling to 150° C., and aspirating air through the apparatus. When ammonium salts are present, the liberated carbon dioxide should be dried by means of sulphuric acid; it is not advisable, in this case, to condense the moisture. From 7 to 18 c.c. of 70% glycerin is required for each 0.1 g. of carbonate.—W. P. S.

Soda-lime as an absorbent for industrial purposes. R. E. Wilson. *J. Ind. Eng. Chem.*, 1920, 12, 1000—1007.

The absorptive capacity of soda-lime is, in general, inversely proportional to its hardness, the latter apparently depending upon the formation of sodium silicate, which tends to clog the pores of the material. This tendency is not directly proportional to the amount of silica in the lime, but to differences in its reactive power. Limes containing over 5% of magnesium oxide are less absorptive than those rich in calcium. A low content of carbon dioxide and ferric oxide is desirable. Extra fine lime yielded granules which were harder, but less absorptive than those from lime of normal fineness. Completeness of hydration appears important to insure stability and hardness of the granules. Up to 5% alkali content the hardness of soda-lime increases greatly with the addition of the alkali, but beyond 6% there is a slight but distinct decrease in hardness. For soda-lime in gas-masks an alkali content of 5% (dry basis) and water content of 10—13% is the most desirable for gases in general. For the absorption of carbon dioxide in steel analyses, oxygen helmet apparatus, etc., an alkali content of 4.5% and water content of 16—19% appear to be the best. For chlorine absorption 8—9% alkali might be used. A greater proportion would be liable to cause trouble from caking. If 2% of kieselguhr is used the optimum alkali content for general purposes is about 3% instead of 5%, but the increase of hardness thus obtained is at the expense of the absorptive capacity.—C. A. M.

Chlorate and perchlorate formation; Theory of electrochemical —. N. V. S. Knibbs and H. Palfreeman. *Faraday Soc.*, June, 1920. [Advance proof.]

RESULTS of the measurement of the conductivities of chlorate, chloride-chlorate, and chlorate-perchlorate solutions, the velocity constants of the reaction hypochlorite to chlorate, and the resistance and potential effects in technical cells are given, the data on conductivities and on the dynamics of the hypochlorite-chlorate reaction covering a wider range than any previously published. The gener-

ally accepted theory of chlorate formation of Foerster and Müller (J., 1903, 417) is reviewed, and the loss of efficiency in technical working is shown to be due mainly to discharge of hypochlorite ions. Regulated addition of hydrochloric acid was found to be the most satisfactory method of maintaining hypochlorous acid concentration. Insoluble impurities in the electrolyte increase the resistance of the solution and therefore the cell voltage, reduce the current efficiency by facilitating the loss of hypochlorous acid, and exert an erosive action on the electrodes, the last effect being of special importance when platinum anodes are used. The two theories of perchlorate formation advanced by Oechsli (J., 1903, 1248) and by Bennett and Mack (Trans. Amer. Electrochem. Soc., 1916, 29, 323) are discussed, and neither is considered to be adequate. It is maintained that perchlorate formation is due to chlorate ion discharge, and a mechanism similar to that of persulphate formation is suggested. The factors in the current efficiency of technical perchlorate formation are discussed, and chloride formation is shown to take place during electrolysis and to be dependent upon the temperature.—B. N.

Aluminates of sodium. Equilibria in the system $\text{Na}_2\text{O}-\text{Al}_2\text{O}_3-\text{H}_2\text{O}$. F. Gondriaan. Proc. K. Akad. Wetensch., 1920, 23, 129—142.

At 30° C. two stable aluminates occur in the system $\text{Na}_2\text{O}-\text{Al}_2\text{O}_3-\text{H}_2\text{O}$, viz., $4\text{Na}_2\text{O} \cdot 3\text{Al}_2\text{O}_3 \cdot 16\text{H}_2\text{O}$ and $4\text{Na}_2\text{O} \cdot \text{Al}_2\text{O}_3 \cdot 10\text{H}_2\text{O}$. Both forms inconspicuously saturated solutions, i.e., are decomposed by water and dilute sodium hydroxide solutions. According to the mode of preparation aluminium hydroxide may be obtained in different forms. Under special conditions alumina forms a crystalline hydrate, $\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$. The gelatinous hydroxide must be considered as a metastable phase of variable composition. It adsorbs variable quantities of alkali. There is probably a continuous transition between these gelatinous hydroxides and the crystalline hydrate. Aluminium oxide is metastable at 30° C. in respect to the hydrate. The swelling exhibited by desiccated particles of the hydroxide and oxide is dependent on the alkalinity of the solution.

—J. R. P.

Calcium oxide; Extraction of — from calcined magnesite. L. H. Duschak. Chem. and Met. Eng., 1920, 23, 628.

CALCIUM oxide may be almost completely extracted from magnesite after calcining at 900°—950° C., by leaching for several hours with water free from carbon dioxide. If the magnesite has been calcined at higher temperatures, and especially if it is "dead-burnt," the extraction is very incomplete and is not improved by fine grinding, probably owing to the formation of an insoluble compound.

—A. R. P.

Zinc sulphide; Influence of crystalline form, flux and actual fusion on the phosphorescence of —. E. Tiede and A. Schleede. Ber., 1920, 53, 1721—1725.

NEITHER crystalline form of zinc sulphide in the pure state is phosphorescent, but when the pure sulphide is fused (cf. *supra*) it becomes strongly phosphorescent. The effect of a flux such as potassium chloride in inducing phosphorescence in zinc sulphide is therefore not due to the formation of a definite crystalline form, but to the lowering of the melting point. The pure fused sulphides of the alkaline-earth metals are also phosphorescent. (Cf. J.C.S., Dec.)—E. H. R.

Zinc, cadmium, and mercury sulphides; Fusion of —. E. Tiede and A. Schleede. Ber., 1920, 53, 1717—1721.

THESE sulphides, which sublime without melting under atmospheric pressure, were fused by heating

in a carbon-tube furnace under pressure in an atmosphere of nitrogen. Zinc sulphide melted under 100—150 atm. at 1800°—1900° C.; the fused solid had a light greenish-yellow lustrous appearance and proved to be the hexagonal modification. Cadmium sulphide melted at about 1750° C. under 100 atm.; it had a dark brownish-yellow lustrous appearance when solidified. Mercuric sulphide was fused at 1450° under 120 atm.; it formed a matt, steel grey solid which quickly became red when rubbed.—E. H. R.

White arsenic; Manufacture of —. E. C. Williams. Eng. and Min. J., 1920, 110, 671—673.

To obtain a pure, dense arsenic trioxide from blast-furnace flue dust and Cottrell plant dust careful regulation of the draught on the furnace from which the arsenic trioxide is sublimed, and efficient and quick cooling are essential. To accomplish this, the cooling chambers should be as deep as possible and their width should increase away from the furnace, with which they should be connected in a straight line by a flue, 2 ft. 6 in. square and about 20 ft. long.—A. R. P.

Tin; Precipitation of — by iron. I. M. Kolthoff. Rec. Trav. Chim., 1920, 39, 606—608.

WHILE agreeing with Bouman (J., 1920, 569a) that under certain conditions iron is capable of precipitating tin from solution, the author concludes from his own experiments that such precipitation does not occur in hydrochloric acid solution.—W. G.

Hydrogen cyanide; New synthesis of — by catalysis. A. Mailhe and F. de Godon. Sealed packet 223, 28.2.18. Bull. Soc. Chim., 1920, 27, 737—739.

WHEN carbon monoxide and ammonia are passed together over thoria at 410°—450° C., an excellent yield of ammonium cyanide is obtained.—W. G.

Cyanic acid; Detection of —. R. Fosse. Comptes rend., 1920, 171, 635—637.

IF the solution shows an increase in urea content, as evidenced by an increase in the weight of xanthylurea obtained in the xanthidol test, after heating with ammonium chloride for 1 hr., cyanic acid is present. A second method is to precipitate the cyanic acid as silver cyanate. The precipitate is divided into two parts; one is heated directly with aqueous ammonium chloride, the other is first heated with nitric acid and then with ammonium chloride. Both solutions are then tested for the presence of urea by means of xanthidol. A positive result with the first solution and a negative result with the second is evidence of the presence of cyanic acid in the original solution.—W. G.

Silicic acid; A new form of —. R. Schwarz and O. Liede. Ber., 1920, 53, 1680—1689.

By leading silicon fluoride into boiling water a new form of silicic acid was obtained, for which the term β -silicic acid is proposed. It dissolves less readily in hydrofluoric acid or in sodium hydroxide or ammonia solution than the normal α -acid. Conductivity experiments on solutions of the β -acid in ammonia indicate that it is a more highly polymerised form, analogous in some respects to meta-stannic acid. (Cf. J.C.S., Dec.)—E. H. R.

Lead hydride. F. Paueth and O. Nörring. Ber., 1920, 53, 1693—1710.

By methods similar to those employed for the detection of the hydrides of bismuth (Ber., 1918, 51, 1704, 1728) and tin (Ber., 1919, 52, 2020), the existence of a gaseous hydride of lead has been proved. The hydride was first prepared by the action of dilute hydrochloric acid on an alloy of bismuth and radio-lead (thorium B); a minute

trace of lead hydride in the resulting gas was detected by a test similar to the Marsh test for arsenic. The lead hydride could not be obtained by the action of acids on ordinary lead-magnesium alloys, but traces were obtained by a combined electrolysis-spark process. (*Cf.* J.C.S., Dec.)

—E. H. R.

Hydrides; Which elements form gaseous —?
F. Paneth. Ber., 1920, 53, 1710—1717.

THE discovery of volatile hydrides of tin, lead, bismuth, and polonium makes it possible to divide the periodic table into two portions, such that all the elements in one portion, and only one element, boron, in the other portion, form volatile hydrides. In other words, the four elements immediately preceding a noble gas in the table, and, in addition, boron, all form volatile hydrides. (*Cf.* J.C.S., Dec.)

—E. H. R.

Radium; Microchemical reactions of —: its differentiation from barium by iodic acid. G. Demigès. Comptes rend., 1920, 171, 633—635.

ALTHOUGH radium salts give results identical with those of barium salts in most microchemical tests for barium, these two series of salts may be differentiated by the use of iodic acid (J., 1920, 469 A). With this reagent the salts of the two metals give definite and distinctly different microcrystalline precipitates, providing the concentration of the salt solution does not exceed 0.3%.—W. G.

Gases; Examination of naturally occurring —.
F. Henrich. Ber., 1920, 53, 1940—1949.

METHODS for collecting and analysing natural gases are described, and particularly an apparatus for removing nitrogen from the rare gases. By circulating through a tube containing a mixture of calcium and sodium in the ratio 10:1, heated to 500° C., in 10 to 15 mins. the whole of the nitrogen can be removed from, for example, a mixture containing 1% of argon. The gas from a cold spring near Leupoldsdorf, Bavaria, was found to contain 13% of oxygen, 86% of nitrogen, and 1% of rare gas, chiefly argon. (*Cf.* J.C.S., Dec.)

Magnesium ammonium phosphate. Kunz-Krause. See XXIII.

PATENTS.

Nitric acid; Production of — [from ammonia].
General Chemical Co., Assees. of F. W. de Jahn. E.P. 124,759, 28.2.18. Conv., 3.11.17.

PURIFIED ammonia is oxidised by mixing it with air and passing the mixture over a catalyst. The nitrogen oxides formed are cooled and partly condensed, after which the residual gases are absorbed by water. The dilute nitric acid produced both by condensation and absorption is conducted into a tower packed with suitable trays containing hot sulphuric acid, and is vaporised by a downward stream of sulphuric acid, the vapours passing from the top of the tower to a condensing system. Nitric acid containing 97% HNO₃ is obtained by this process.—W. J. W.

Nitric acid and sulphuric acid; Apparatus for the recovery of — from waste acids. C. F. Baer. G.P. 323,416, 27.2.19.

A DENITRATION plant comprises a tower built up of sections with superposed, perforated plates arranged internally at 5—7.5 mm. distance from the walls. The plates have large central openings for the

passage of nitrous vapours, and smaller ones for the sulphuric acid flow, with partition walls between the sets of openings dividing the plates into two parts.—W. J. W.

Sulphuric acid and hydrochloric acid; Process of obtaining — from alkaline-earth salts. J. Behrens. G.P. 303,922, 30.6.17.

ALKALINE-EARTH salts are caused to interact with a weak basic oxide in a neutral salt solution and in presence of carbon dioxide. The alkaline-earth carbonate formed is separated and the metallic salt is decomposed by suitable means. Sulphuric anhydride is thus produced by introducing calcium sulphate into ferrous sulphate solution containing reduced ferrous oxide, and passing in carbon dioxide. Air is then blown through the filtered solution, and the ferric sulphate is decomposed. For the production of hydrochloric acid magnesium chloride is made to react with aluminium hydroxide in aluminium chloride solution.—W. J. W.

Automatic control of the production of a product [e.g., sulphuric acid by the contact process]; Means for — depending on the change produced in radiant energy by the presence of undesirable substances in the initial material. L. Logan. E.P. 151,328, 18.6.19.

LIGHT or other radiant energy is thrown upon a surface or container adapted to receive an automatically taken sample of the material to be controlled. A selenium or potassium-sodium alloy cell responds to changes in the transmitted light and regulates the supply of the material. For example, in the contact process for sulphuric acid the supply of burner gas can be automatically by-passed if arsenic is present by utilising the mirror of arsenic deposited in the Marsh test to intercept the light. The device is also applicable to impurities which alter the specific rotatory power or refractive index of a liquid, or which yield a coloured product with chemical indicators.—C. I.

Alkali aluminates; Preparation of pure —.
Rochette Frères. E.P. 141,666, 3.12.19. Conv., 16.4.19.

LIME or baryta and bauxite are fused with carbon in an electric furnace. Pure calcium or barium aluminate is formed and floats on the top, and a ferrous alloy containing silicon, titanium, etc., is drawn off at the bottom. From the calcium or barium aluminate alkali aluminates are obtained by interaction with alkali carbonate.—C. I.

Alkali silicates; Manufacture of readily soluble —.
F. J. Phillips and E. J. Rose. E.P. 151,339, 19.6.19.

A MIXTURE of silica and alkali containing 3 pts. of SiO₂ to 1 pt. of Na₂O or K₂O is mixed with 0.5—10.0% of borax and fused. The mass in a viscous state is rolled, dropped into water, and ground till dissolved. Sulphuric or other acid is then sprayed into the solution with continuous agitation until the gelatinous silica is redissolved, and the solution is evaporated.—C. I.

Comminution and mixing of materials [alkali silicates]. F. J. Phillips and E. J. Rose. E.P. 151,508, 28.11.19.

PARTIALLY disintegrated alkali silicate is introduced with water into a closed rotating cylinder, the axis of which is formed of a perforated pipe through which steam is supplied. The steam pipe may be surrounded by a perforated sleeve, and the perforations in the two pipes may be caused to register or not as desired. A safety valve may be provided to maintain a predetermined steam pressure in the cylinder.—B. M. V.

Absorbent [soda-lime]. R. E. Wilson. U.S.P. 1,333,524, 9.3.20. Appl., 15.11.18.

SODA-LIME in the form of hard, uniform grains, specially efficient as an absorbent, and offering low resistance to the passage of gases, is prepared by mixing 300 lb. of slaked lime with 60 lb. of a 20% solution of sodium hydroxide and 120 lb. of water, forming the mixture into slabs, 1½ in. thick, drying till the water content is reduced to 14%, allowing to cool for several hours, grinding, and screening to 8—14-mesh size.

Potassium chloride; Process for obtaining — [from furnace dust]. E. Anderson and F. S. Moon, jun., Assrs. to International Precipitation Co. U.S.P. 1,354,642, 5.10.20. Appl., 8.3.19.

FURNACE dust containing potassium sulphate and chloride is washed with calcium chloride solution to convert the potassium sulphate into chloride, after which the solution is separated from solid matter and the potassium chloride recovered.—W. J. W.

Potassium chloride; Method of recovering — from brine. J. L. Silsbee. U.S.P. 1,353,283, 21.9.20. Appl., 22.10.19.

BRINE containing sodium, potassium, and magnesium chlorides is evaporated at atmospheric temperature until nearly saturated with respect to potassium chloride, and after separating precipitated sodium chloride is further concentrated at atmospheric temperature to precipitate mixed chlorides of potassium and sodium without precipitating magnesium salts.—C. I.

Nitrogen compounds [cyanides] Process of forming —. C. B. Jacobs, Assr. to Air Reduction Co., Inc. U.S.P. 1,354,561, 5.10.20. Appl., 19.8.16.

CARBONACEOUS material, such as coke, is intimately mixed with an alkali metal compound, and the mixture, while in a pulverulent condition, is heated to expel its volatile constituents. The porous coke, enclosing the alkali metal compound, is then heated to, and maintained at, an elevated temperature, and nitrogen is introduced into the mixture.

—W. J. W.

Ammonia; Production of — [from crude cyanides]. F. J. Metzger, Assr. to Air Reduction Co. U.S.P. 1,354,574, 5.10.20. Appl., 15.10.18.

CYANIDE furnace products containing iron are subjected to the action of dry steam at a temperature above that of condensation of the steam and below 500° C., whereby loss of ammonia by formation of ferrocyanide is prevented.—A. de W.

Nitre-cake; Process of obtaining a liquid of high acidity from —. W. C. Holmes, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,354,649, 5.10.20. Appl., 27.11.18.

By continuous treatment of nitre-cake with water in such quantities as to prevent complete solution, a solution of 20—30% acidity is obtained.

—W. J. W.

Bismuth oxide; Making —. E. R. Darling, Assr. to Ellis-Foster Co. U.S.P. 1,351,806, 5.10.20. Appl., 4.1.19.

YELLOW bismuth oxide is prepared by fusing bismuth with sodium nitrate and passing chlorine into the fused material.—C. I.

Aluminium chloride; Method of manufacturing —. F. C. Frary, Assr. to Aluminium Co. of America. U.S.P. 1,354,818, 5.10.20. Appl., 26.5.20.

CHLORINE and a reducing agent are added to a pulverulent mass of aluminium dross.—C. I.

Aluminium compounds for sizing papers and other purposes; Preparation of —. G. Muth. G.P. 323,626, 19.8.19. Addn. to 319,420 (J., 1920, 517 A).

AN excess of acid substances is employed in decomposing the original material, and the excess is afterwards so far neutralised that the final product remains liquid. Neutralisation is effected by means of magnesium oxide or carbonate or materials containing these, or with mixtures of magnesium compounds with basic compounds of the alkaline earths or alumina, e.g., aluminates or soluble aluminium hydroxide.—J. H. L.

Alkali sulphates; Manufacture of — from alkali chlorides by decomposition with alkaline-earth sulphates or magnesium sulphate. Salzwerk Heilbronn, G. Kassel, and T. Lichtenberger. G.P. 299,775, 11.6.15. Addn. to 289,746 (J., 1920, 405 A).

A MOLTEN mixture of alkali chlorides and sulphates of the alkaline earths or magnesium is superheated and agitated with steam, after which it is allowed to settle, and the pure alkali sulphate is separated from the residual alkaline-earth oxido or magnesia.

—W. J. W.

Cyanamide solutions; Manufacture of — from crude calcium cyanamide. H. Danneek, and Elektrizitätswerk Lonza, A.-G. G.P. 302,495, 13.3.17.

CRUDE calcium cyanamido is treated with carbon dioxide, or gases containing it, before being mixed with water.—W. J. W.

Amides of alkalis and alkaline earths; Manufacture of —. Badische Anilin- und Soda-Fabrik. G.P. 323,656, 24.5.14.

DRY ammonia gas is passed into solutions of alkali or alkaline-earth metals in anhydrous caustic alkalis. As the formation of amides takes place at about 275° C., loss of ammonia through dissociation is avoided.—W. J. W.

Sodium percarbonate; Preparation of a substance containing — from sodium peroxide and carbon dioxide. L. Schwedes. G. P. 324,569, 1.1.18.

CARBON dioxide is passed into a paste of sodium peroxide and alcohol. The heavy yellow peroxide changes to a white flocculent mass containing 50% of percarbonate with about 7% active oxygen.

—C. I.

Sulphur; Process for obtaining — from hydrogen sulphide, or mixtures containing it. Chem. Fabr. Rhenania, and F. Projahn. G.P. 298,844, 1.2.16.

THE gases to be treated are passed downwards through a layer of contact material, such as bauxite, of 30 cm. thickness, at about 330° C., and then through a lower layer of such greater thickness as to allow the gases to cool down to the desired minimum temperature, approximately 200° C. A conical heap of the same contact material may be placed round the charging hole of the furnace. The main reaction, $H_2S + O = H_2O + S$, proceeds most favourably at 300° C. The injurious secondary reaction $2H_2O + 3S = 2H_2S + SO_2$, is only feeble at 200° C., and in the lower layer of the contact material is largely replaced by the reaction $2H_2S + SO_2 = 2H_2O + 3S$.—W. J. W.

Sulphuric acid; Concentration of —. A. C. Bohre; K. C. Bohre, extrix., Assr. to Norsk Hydro-Elektrisk Kvaelfstofaktieselskab. U.S.P. 1,353,448, 21.9.20. Appl., 27.3.19.

VIII.—GLASS; CERAMICS.

PATENTS.

Glass; Reduction in size of the bubbles contained in —. Schott und Gen. E.P. 147,487, 8.7.20. Conv., 7.12.14.

THE glass is subjected, when in the softened state, to a pressure of at least 200 atm. The reduction in size of the bubbles is partly due to the compression of the gases forming the bubbles, and partly to the absorption of the gases by the glass. —H. S. H.

Kilns. T. West and J. Hodgson. E.P. 151,709, 26.6.19.

THE kiln chamber is divided by partitions into five spaces, with fire-grates adjoining the outer spaces. The heating gases enter the latter near the top, descend, pass up through perforated floors into the intermediate spaces, and thence down the central chamber. From the bottom of this central space four flues extend to the top of each other chamber. Part of the heating gases from the central chamber passes through these flues and is used over again in the outer and intermediate chambers. Air enters under the fire-grate, passes up a hot air flue and enters the outer spaces at the top. Hot air is also allowed to enter the central chamber to mix with the heating gases which are conveyed by the four return flues to the outer chambers. Air flues above the fire-grate enable the process of "salting" to be carried out. —H. S. H.

Ovens; Continuous and intermittent —. Dressler Tunnel Ovens, Ltd., and J. Williamson. E.P. 151,722, 27.6.19.

TWO burners are placed at the middle of the length of the oven and on opposite sides of the goods spaces. They are fired from gas producers which form part of the side walls of the oven. Hot air can be supplied to the burners from the interior of the oven. The hot gases pass into heat accumulators built at the sides of the oven, and containing refractory chequerwork. These chambers are connected with an exhaust fan by means of horizontal pipes freely exposed to the interior of the oven at the inlet end, so that heat from the waste gases effects the preliminary heating of the goods. The heat accumulators are provided with inlet and outlet dampers which enable a transverse current of air, heated by the accumulator, to enter the oven and flow round the goods. When these dampers are closed the hot gases from the burner heat up the accumulator and pass to the

chimney. By means of reversing valves and dampers it can be arranged that one accumulator is heating up while the other discharges hot air into the oven. A more uniform and a higher temperature is attained by means of these devices, without increasing the amount of fuel used. When required, material for salt glazing is injected into the heat accumulator immediately after it is put into connexion with the oven. An oxidising or reducing atmosphere can be produced in the oven at will. —H. S. H.

Decorating kiln and the like. M. Solon, Assr. to The Potters Equipment Co. U.S.P. 1,354,518, 5.10.20. Appl., 8.12.17.

THE kiln is provided with heating flues in opposite walls, each flue having a heat supply connexion and an outlet connexion. A by-pass heating flue, placed in one of the outer walls, has its upper end connected with the other flues near the supply connexion, and its lower end connected with the same flues near the outlet connexion. —H. S. H.

Tunnel-kiln. P. Dressler, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. 1,354,541, 5.10.20. Appl., 22.1.19.

COMBUSTION chambers are arranged on each side of the interior of the inclosing structure of a tunnel kiln. Each combustion chamber is divided into two sections connected by a sleeve, which permits relative movement between the sections. Means are provided for introducing gas and highly heated air into one section of each chamber, and of projecting the gases longitudinally into the adjacent section of the chamber. —H. S. H.

Glass bait. E. C. R. Marks. From Universal Glass Co. E.P. 151,361, 23.6.19.

Glass; Manufacture of plate and other window — and apparatus therefor. J. Ramsey. E.P. 151,543, 13.3.20.

Glass gathering and blowing machines. W. E. Evans. From Europaischer Verband der Flaschenfabriken Ges. E.P. 151,831, 16.10.19.

IX.—BUILDING MATERIALS.

PATENTS.

Wood; Preserving and fireproofing of —. I. De Vecchis. E.P. 151,661, 3.3.19.

THE wood is placed in a hermetically sealed container and the sap removed by reducing the pressure. A little free alkali is added to a solution of double sulphates or chlorides of copper, zinc, and magnesium with ammonium, and a suitable anti-septic, and the solution is sucked into the container, which is then subjected to a pressure of 8 to 14 atm. The wood after removal is air-dried until it has been reduced to the weight which it would have had if it had been seasoned in the ordinary way. —H. S. H.

Road-making or paving materials, and method of manufacturing the same. C. Honda. E.P. 151,852, 15.11.19.

ROAD-MAKING or paving materials are made by mixing tarry matter with table salt, rosin saponified with slaked lime, and rosin sulphuretted with sulphur powder, clay being also added if desired. The salt increases the viscosity of the tar and improves its impregnating and solidifying power, the

saponified rosin acts as a binding material, and the sulphuretted rosin protects the surface from being affected by temperature changes.—H. S. H.

Calcium-sulphate products [plaster]; Retarder for —. F. E. Culver. U.S.P. 1,330,058, 10.2.20. Appl., 17.3.19.

The setting of plaster or the like is retarded by addition of vegetable gluten dissolved in potassium or sodium hydroxide solution and mixed with lime.

Cement raw materials; Treatment of —. H. Cappenberg. G.P. 323,290, 29.1.19.

Dry ferric chloride, or a mixture of aluminium chloride and ferric chloride, or a solution of both salts, is added to cement raw material before burning. The salts promote the evolution of carbon dioxide from the material, and a porous clinker is obtained.—W. J. W.

Concrete blocks, slabs, etc.; Manufacture of —. G. Schalk. G.P. 323,526, 12.4.19.

Pumice sand heated to 1000° C. is mixed with sand etc. in a drying and mixing machine, and the product is incorporated with a prepared mixture of cement and water at about 80° C.—W. J. W.

Light concrete for ship-building; Process for manufacturing —. A. Hambloch. G.P. 323,643, 13.3.19.

VOLCANIC sand, pumice, tufaceous limestone, or granulated slag is mixed with lime and formed into lumps by shaking, after which these are hardened by means of steam under pressure, reduced to small size, and mixed with cement.—W. J. W.

Potland cement; Utilisation of low grade carboniferous material in manufacture of —. R. W. Lesley. E.P. 152,106, 4.7.19.

SEE U.S.P. 1,323,294 of 1919; J., 1920, 65 A.

Sulphite - waste - liquor preparation. U.S.P. 1,327,862. See V.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron ores; Microscopical examination of — with special reference to its value in dressing processes. H. Schneiderhöhn. Stahl u. Eisen, 1920, 40, 1261—1265.

THE author recommends the use of the microscope to investigate the nature of raw materials, products, and working methods. It is of service in determining if the concentration of low-grade ores is an economical proposition, in determining mineralogical composition, and in ascertaining whether ores are suitable for magnetic separation. It has also proved of value in determining the iron content of mixed iron ores. From the microscopical appearance the nature of the gangue can be ascertained, and hence its specific gravity and probable behaviour in wet mechanical separation. Separation processes may be controlled by microscopical examination of the products at different stages, and the method of combination of valuable and useless components in iron ores, e.g., the form in which manganese and phosphorus are present, may be ascertained. The microscope is also of service in examining the structure and intermixture of crushed and intermediate products, in controlling the briquetting and agglomeration of concentrates, and in the examination of slags.—T. H. Bu.

Blast-furnace gas; Rough-cleaning of — at Skinningrove by the Lodge electrostatic process. A. Hutchinson and E. Bury. Iron and Steel Inst., Sept., 1920. [Advance proof.] 18 pages.

THE electrostatic plant is divided into sixteen cleaning units, each with two discharge grids placed in series. This multiplicity of chambers was adopted to ensure maximum contact between the electrostatic discharge and the gas to be cleaned by splitting up the gas flow into multiple streams; also to avoid passing large quantities of dirty gas into the system when cleaning the chambers (during which operation the discharge must be cut off), which would have been the case if a smaller number of larger chambers had been employed. The pressure employed is 40,000 volts. The entire make of gas from 3000 tons of pig iron per week is treated with a consumption of 50 kw. Each cleaning chamber is provided with two cleaning hoppers, into which the dust is shaken from the grids by rappers. The dust content of the gas is reduced from 5–6 g. to 0.8–1.1 g. per cb. m. with 15–20% of the plant not yet in action. When the plant is complete it should be possible to keep down the dust content to 0.5–0.7 g. per cb. m. The dust (recovery, 48–50 tons per week) is removed every 8 hrs. and is taken to the potash extraction plant by scraper conveyors. The potash extraction plant consists of mixers for lixiviating the soluble salts from the dust, revolving filters for separating the soluble matter from the solution of chlorides, and two Kestner evaporators. Potassium and sodium chlorides are separated by fractional crystallisation from calcium chloride, and potassium chloride is further fractionated from sodium chloride. The potassium chloride recovered amounts to 27% of the dust. The sensible heat of the gas is not greatly diminished, the temperature of the raw gas being 220°–250° C. and of the cleaned gas 200°–220° C.—A. G.

Soft iron. F. Goerens and F. P. Fischer. Elektrochem. Zeits., 1920, 27, 1–5, 11–16.

TESTS were made on a soft iron prepared by the open-hearth process and having an average composition C 0.057%, Si 0.01%, Mn 0.097%, P 0.01%, S 0.021%. The structure consisted of coarse ferrite crystals which increased in size towards the edge. Tests on rolled and forged bars and plates gave an average yield point of 21 kg., a breaking stress of 31 kg., an elongation of 47%, and a contraction of 80%, and compared favourably with tests made on copper bars. Impact tests on differently notched bars gave good results, and bending tests with plain and screwed bars were also satisfactory, the results being similar to those obtained with copper. Repeated bending tests gave a superior figure to similar tests on copper, while welded bars bent through 180° without fracture. Incorrect heat treatment or work developed a coarse crystalline structure resulting in brittleness, but this could be avoided or removed by reheating at temperatures not less than 920° C.—J. W. D.

Gases from iron made by various processes. E. Piowarsky. Stahl u. Eisen, 1920, 40, 1365–1366.

THE author has determined the percentage composition of the gases given off by Thomas pig iron, avoiding the experimental error of allowing access of air to the molten metal by the use of a special chill mould. A stream of nitrogen was passed through the top of the mould while it was filling with metal, thus preventing action between the carbon of the pig iron and the oxygen of the air. Samples of the gases were taken at the beginning, middle, and end of tapping, five being taken in each case at intervals of a minute. The composition of the gases at these three stages was: CO, 0.40–0.85, 0.45–0.74, 0.30–0.48; CO₂, 24.0–31.4, 36.1–41.9, 42.2–43.9; H₂, 30.8–49.6, 42.8–49.7;

44.1—48.3; and N_2 , 18.6—44.3, 9.8—19.8, 9.1—12.5% respectively. In the most favourable cases the sum of the hydrogen and carbon monoxide amounted to 88.5%, while in Munker's experiments (Stahl u. Eisen, 1904, 23) 70% was reached only in the case of spiegel. Very little gas was given off after the pig iron had solidified.—T. H. Bu.

Steel; Physical properties of arc-fused — H. S. Rawdon, E. C. Groesbeck, and L. Jordan. Chem. and Met. Eng., 1920, 23, 677—684.

TEST specimens were machined from blocks of arc-fused metal, built up by depositing the fused metal as a series of "beads," so arranged that they were parallel with the axis of the tension specimen which was cut later from the block. Two series, representative of a "pure" iron and a low-carbon steel, as used for welding electrodes, were examined. The general effect of the fusion was to render the two materials more nearly of the same composition, due chiefly to the loss of carbon and silicon by oxidation. A slight coating on the electrode before fusion had little influence in preventing this oxidation. The most noticeable change in composition was the increase in nitrogen content of the metal, following roughly the increase in current density. All the specimens contained a considerable number of cavities and oxide inclusions and no definite relation between "soundness" and current density within the range employed was shown. When stressed in tension, low ductility values were given; the elongation of the test specimen appeared to be a measure of the adhesion between the successive added layers, being due largely to the cumulative effect of numerous imperfections rather than to the real property of the metal itself, which, judged by its behaviour on bending, was inherently ductile. It is seemingly impossible to fuse the metal without serious imperfections, which are so gross that the changes in chemical composition which the fusion entails, together with the accompanying unusual features of micro-structure, are of minor importance in determining the strength, durability, and other properties of the arc weld.

—C. A. K.

Corrosion of iron and steel; Influence of copper, manganese, and chromium on the — E. A. and L. T. Richardson. Trans. Amer. Electrochem. Soc., 1920, 123—135. [Advance copy.]

COPPER and manganese have a mutual action in their effect on the atmospheric corrosion of iron. Copper alone reduces the corrosion of pure iron, and to a still greater extent that of steel containing manganese, the latter enhancing the effect of the copper. If manganese is replaced by chromium the effect is still more pronounced. The authors consider that in commercially pure iron the presence of copper produces an inter-grain film of oxide or other compound of iron, and that this film confers rust-resisting properties on the iron. Between 800° and 1000 C. this inter-grain material becomes weak and plastic, producing red-shortness in the iron. Additions of manganese and chromium result in a smaller grain size and consequently increase in resistance to corrosion. These elements also lower the red-short range of temperature, and if present in sufficient quantities this range occurs at a temperature below that at which the inter-grain film becomes weak or plastic.—J. W. D.

Metals; Solution of — in acids as related to corrosion. W. D. Richardson. Trans. Amer. Electrochem. Soc., 1920, 153—186. [Advance copy.] (Cf. J., 1920, 600 A.)

CORROSION and solution of metals in acids may be considered as actions tending to go forward at rates proportional to solution tension and hydrogen ion concentration, but subject to the accelerating and retarding influence of many substances acting as

catalysts. Cast metals are relatively less attacked in the presence of much oxygen than the purer rolled metals. They are also relatively less attacked by an oxidising acid, such as nitric acid, than by the non-oxidising sulphuric and hydrochloric acids. Silver, copper, and formaldehyde, as catalysts, all reverse this action and cause the rates of solution of the cast metals in nitric acid to be increased and the rates of solution of copper-bearing and pure open-hearth irons to be reduced. Platinum, while catalysing the rolled metals negatively in nitric acid, catalyses them positively in sulphuric and hydrochloric acids, and is without action on the cast metals in any acid. Nickel as a catalyst produces no effect on any of the metals in any of the acids except on aluminium in hydrochloric acid, in which case the rate of solution is greatly increased. Aluminium is not affected by any of the catalysts in nitric or sulphuric acids.—J. W. D.

Zinc retorts; Determination of the thermal condition of the charge in — O. Mühlhaeuser. Metall u. Erz, 1920, 17, 209—212.

DURING a zinc distillation the temperatures of the retort and combustion chamber were recorded at the end of each half-hour. On charging the retort the temperature of the combustion chamber falls rapidly at first, remains constant at about 1050° C. for a considerable time, and then rises slowly to the maximum (1300° C.). The temperature of the retort charge rises slowly to about 1000° C., where it remains constant for some hours due to the reduction of the zinc oxide to metal, which reaction absorbs 89,600 cal. The temperature then slowly rises while the zinc distils, to a maximum 100°—150° C. below that of the combustion chamber.—A. R. P.

Zinc distillation; Determination of the quantity of gas evolved during — O. Mühlhaeuser. Metall u. Erz, 1920, 17, 415—420.

TABLES and graphs are given showing the temperature and pressure in the retort and the volume and nitrogen content of the gases evolved during the progress of the distillation of zinc from zinc oxide (roasted blende) and anthracite. The rate of evolution of the gases is greatest at the commencement of the operation, when the temperature of the retort has reached 1000° C., and falls rapidly during the next two hours, after which it again rises with the rise in temperature to a second maximum, which, however, is much lower than the first. The rate then gradually decreases until the end of the distillation. The nitrogen content of the gases is at a maximum at the beginning, then slowly decreases until the middle of the distillation, after which it again rises to a maximum at the end of the operation.—A. R. P.

Aluminium casting alloys; Rapid method for the analysis of light — R. M. Berry. J. Ind. Eng. Chem., 1920, 12, 998—1000.

THE alloy (1 g.) is dissolved in 20 c.c. of 25% sodium hydroxide solution, the solution immediately diluted to 300 c.c., and filtered and the insoluble residue (containing Sn, Cu, Pb, Fe, Ni, Mg, part of the manganese, and traces of aluminium) washed at least ten times with 1% sodium hydroxide solution. The filtrate (containing about 99% of the aluminium and zinc, and the remainder of the manganese) is treated with formic acid to give an excess of 25 c.c., and then with hydrogen sulphide to precipitate the zinc as sulphide, which is dissolved in acid and the solution titrated with ferro-cyanide. The original alkali-insoluble portion is digested with nitric acid and the tin extracted from the residue by means of ammonium sulphide and chloride solution, and precipitated as sulphide, which is ignited to SnO_2 . The nitric acid solution is electrolysed to determine copper and lead, the

iron and aluminium separated from the exhausted electrolyte, and the iron determined by titration with permanganate. Nickel is determined in the filtrate from the iron and aluminium by means of dimethylglyoxime, and the magnesium determined in the filtrate from the latter operation by precipitation with ammonium phosphate. To determine manganese the alloy is treated with sodium hydroxide solution and then with nitric acid, and the solution treated with silver nitrate, oxidised by means of ammonium persulphate, and titrated with arsenite solution. Silicon is determined by dissolving the alloy in sulphuric and nitric acids, adding hydrochloric acid, evaporating, extracting the residue with hydrochloric acid, and filtering off and igniting the silica.—C. A. M.

Copper-aluminium alloys or hardeners; Manufacture of rich —. R. J. Anderson. Chem. and Met. Eng., 1920, 23, 617–621.

For the manufacture of rich copper-aluminium alloys containing 33, 50, or 67% Cu, the following method is recommended. About one-third of the aluminium is melted in an iron pot, cold pigs of aluminium are then thrown in to cool the metal, after which a quarter of the molten copper is poured in. The temperature rises owing to the heat of combination of the two metals; more cold aluminium is therefore added until some solid metal is seen floating in the molten alloy. Another quarter of the copper is then poured in and the process repeated until the whole of the metals have been added and thoroughly mixed, when the alloy is poured or ladled into pigs. The eutectic alloy (67% Al, 33% Cu) melts at 540° C., that containing 50% Cu at 575° C., and that containing 60% Cu at 658° C. All the alloys are brittle and may be readily broken up for use in hardening aluminium. —A. R. P.

Ternary alloys and coefficients of equivalence. L. Guillet and A. Portevin. Rev. Mét., 1920, 17, 561–567.

A THEORETICAL and mathematical consideration of the principles governing the influence of the addition of a third metal to a binary alloy such as brass. This addition of a third metal may have the effect of displacing the eutectic point in the diagram to the left or right, so that the resulting alloy under the microscope exhibits a structure corresponding, in the case of brass, to a copper content quite different from its real content of copper. The relation between the two may be expressed by the equation $A' = \frac{100A}{100+q(t-1)}$ where A'

and A are the apparent and real percentages of copper, q is the quantity of the third element added, and t is its coefficient of equivalence, i.e., the proportion of zinc which replaces 1% of the element in the alloy of apparent composition A' . In the triangular diagram of a ternary alloy it is possible to draw isomicrographic lines through points representing the composition of alloys having similar micrographic structures; the general equation of the lines is $\frac{A}{A'} + q \frac{(1-t)}{100} = 1$.—A. R. P.

Molybdenum, cobalt, and chromium alloys; Analysis of —. J. R. Camp and J. W. Marden. J. Ind. Eng. Chem., 1920, 12, 998.

A SMALL quantity of the alloy is dissolved in a few c.c. of *aqua regia*, 3 c.c. of sulphuric acid added, and the liquid evaporated until white fumes appear, diluted to 100 c.c., and transferred to a small pressure bottle. The solution is treated for 5–10 mins. with hydrogen sulphide, and the bottle closed and placed for an hour in boiling water. The

precipitated molybdenum sulphide is washed free from acid, redissolved, reprecipitated and again washed, and finally ignited for 2 hrs. and weighed as MoO_3 . The filtrate is boiled, treated with sodium peroxide, and again boiled, and the precipitated cobalt hydroxide washed with dilute hydrogen peroxide, the black cobaltic hydroxide ignited, and the residue of Co_2O_3 weighed. As a rule it is necessary to dissolve the precipitated hydroxide in dilute hydrochloric acid, and to reprecipitate it. The filtrate is acidified, boiled to remove hydrogen peroxide, and the chromate titrated with ferrous ammonium sulphate solution either by an electrometric method or with potassium ferrieyanide as outside indicator.—C. A. M.

Zinc, cadmium, and mercury sulphides. Tiede and Schleede. See VII.

Thermo-couples. Wilson and Epps. See XXIII.

Zirconium. Smith and James. See XXIII.

PATENTS.

Flotation separation of mineral substances. T. H. Palmer, H. V. Seale, and R. D. Nevett. E.P. 132,260, 3.9.19. Conv., 2.9.18.

ONE containing mixed sulphides is subjected to a flotation treatment in an aqueous medium containing elemental sulphur, added in proportion of 0.5% of the quantity of ore, whereby one of the sulphides is removed, the residue being subjected to further flotation in the same medium with the addition of an acid or a frothing agent or both and with the temperature raised.—J. W. D.

Furnace for the heat treatment of steel, iron, or the like. J. R. C. August. E.P. 151,323, 17.6.19.

A REMOVABLE muffle is supported concentrically within a furnace chamber by a number of firebrick partitions which form flues for the heating gas, the latter being generated by the burning of solid fuel in a fire-box at the rear and introduced by a port-hole into one of the longitudinal flues, or by the burning of liquid or gaseous fuel in a burner placed longitudinally below the muffle. The furnace is wound with electric coils so arranged that the iron or steel inside is located in the magnetic field produced by the current, the critical temperature, i.e., the magnetic change point, being indicated on a galvanometer.—J. W. D.

Tin scruff produced in the making of tin andterne plates; Treating —. G. H. Clegg. E.P. 151,374, 25.6.19.

THE scruff is crushed, agitated with cold water in a tank to dissolve the zinc chloride, and the lighter particles of sludge separated from the zinc chloride in the liquid drawn from the tank by means of a vacuum filter or filter-press. The sludge remaining in the tank is ground and agitated with cold water till pasty, the heavier particles of tin screened off, and the metallic oil soap or "tin soap," consisting of tin oxide, palmitin, and palmitic acid, separated into those constituents by filtration and treatment with hydrochloric acid.—J. W. D.

Sherardizing; Drums for —. S. O. Cowper-Coles. E.P. 151,426, 6.8.19.

A ROTATING drum is fitted with a central longitudinal tube, the annular space around it forming a chamber for the articles to be sherardised and the zinc dust. The tube is heated either by gas jets, electric heating coils, circulating hot oil, or superheated steam, the heat passing into heat-insulated chambers at either end and thence through a series of tubes extending longitudinally through the annular space and through an outer jacket on the drum.—J. W. D.

Sulphide ores; Treatment of argentiferous —. F. E. Elmore. E.P. 151,698, 23.6 and 18.12.19.

THE argentiferous lead-zinc sulphide residue obtained from the acid brine process (E.P. 6546 of 1917; J., 1919, 541 A) is heated with sodium chloride or other suitable halogen salt in the presence of air at a temperature sufficiently high to cause volatilisation of a substantial proportion of the lead as chloride or oxychloride. The silver and the remaining lead are then extracted from the residue by leaching with a strong solution of calcium or magnesium chloride containing hydrochloric acid, cupric chloride, or both, not greatly in excess of that required to convert into chloride the lead present.—J. W. D.

Electrode; Electrical-arc-welding — and process of making. J. Churchward, Assr. to Wilson Welder and Metals Co. U.S.P. 1,333,586, 9.3.20. Appl., 21.7.19.

A "sull finish" or rust coating is formed on a welding rod of iron or the like, which is then immersed in a hot bath of milk of lime and afterwards baked in order to fix the coating of lime.

Briquetting of ores. F. A. Vogel, Assr. to General Briquetting Co. U.S.P. 1,334,331, 23.3.20. Appl., 26.10.18.

IN making ore briquettes with coal as a binding agent the mixture of ore and coal is warmed and dried, mixed with a regulated quantity of a "stimulant," e.g., tar oil, subjected to the action of moisture, and the moistened material subjected to an intimate grinding and mixing operation until it is entirely converted into a "coherable mass possessing a cementing facility," after which the mass is formed into briquettes.

Ores; Process of treating [sintering] —. J. E. Greenawalt. U.S.P. 1,348,408, 3.8.20. Appl., 25.11.12.

FUEL and combustion-supporting gases are projected into a chamber above the charge of ore, the fuel is ignited, and the burning mixture is drawn downwards through the charge of ore.

Zinc-reduction furnace. J. D. Shipton. U.S.P. 1,353,362, 21.9.20. Appl., 10.6.19.

A SERIES of retort tubes extend across the furnace and are connected with a corresponding series of condensers. At the other end each tube is fitted with a door for charging. All the condensers are connected together to form a common condensing surface and means are provided for withdrawing the condensed metal.—J. W. D.

Alloys. F. Milliken, Assr. to F. Milliken, S. F. Weaver, and J. M. Repplier. U.S. Pats. (A) 1,354,988, (b) 1,354,989, and (c) 1,354,990, 5.10.20. Appl., 8.10.19.

THE alloys have the following compositions:—(A) Cu 50–60%, Ni 28–36%, Zn 4–8%, Fe 4–8%; (b) Cu 55–65%, Ni 6–11%, Zn 14–18%, Pb 10–14%; (c) Cu 31–38%, Ni 38–46%, Fe 16–20%, Cr 5–7%, Mn 0.25–0.75%.—J. W. D.

Bauxite; Process of smelting — for production of ferro-aluminium in an electric furnace. Rheinische Elektrowerke A.-G. G.P. 308,542, 7.3.18.

By the addition of calcium compounds, especially lime, to bauxite in the electric furnace, the vapour tension of the alumina is appreciably diminished owing to formation of calcium aluminate, and a slag rich in calcium carbide is obtained as a by-product.—W. J. W.

Aluminium; Production of a brown colour on —. Hirsch, Kupfer- und Messing-Werke A.-G., and L. von Grotthus. G.P. 324,619, 15.11.18.

THE metal is submitted to electrolytic treatment in an ammoniacal solution of ammonium molybdate, through which hydrogen sulphide has been passed until a deep-red coloration has formed. This preliminary treatment facilitates deposition of the molybdenum.—D. F. T.

XI.—ELECTRO-CHEMISTRY.

Lead accumulators in works practice. A. Langer. Chem.-Zeit., 1920, 44, 749–750.

CHARGING accumulators until the plates evolve gas freely is injurious, since energy is wasted, and the cathodes tend to disintegrate. Experiments showed that by careful charging the temperature of the acid may fall slightly. Changes of concentration of the acid in different parts of the cell may occur. Detailed directions for the use of an accumulator battery are given.—J. R. P.

Chlorate and perchlorate. Knibbs and Palfreeman. See VII.

Ilust-furnace gas. Hutchinson and Bury. See X.

PATENTS.

Electric accumulators. G. Marconi. E.P. 151,293, 5.4.18. Conv., 5.4.17.

AN electric accumulator of the zinc-chlorine type comprises a number of porous cylinders contained within a cylindrical steel sheath coated internally with zinc. Each porous cylinder contains a carbon rod and is packed with powdered carbon. The steel sheath is closed below by an insulated cover. The porous cylinders are immersed in an aqueous solution of zinc chloride and chloride of calcium or other alkaline earth or alkali. A layer of zinc-coated wire gauze or carbon grains rests upon the porous cylinders and the solution referred to is poured thereon. A circulating tube is introduced axially into the liquid electrolyte, and contains another tube enclosing a heating coil, which is so connected that during charging and discharging of the accumulator circulation of the electrolyte is effected owing to the heat generated in the coil. The various carbon rods are electrically connected with the insulated bottom cover. The space above the electrolyte is filled with air or hydrogen at a pressure of about 20 atm. The steel sheath and the insulated bottom cover serve as the electrodes of the accumulator.—J. S. G. T.

Carbohydrates [wood]; Process of procuring and securing products from —. Means actuated by alternating electric current for controlling or operating electric furnaces or other mechanisms. J. H. Reid, Assr. to International Nitrogen Co. U.S.P. (A) 1,327,737 and (B) 1,327,738, 13.1.20. Appl., 13.1 and 19.12.14.

(A) A MIXTURE of a carbohydrate (wood, sawdust) and a metal oxy-compound (lime, calcium carbonate) is exposed to successive stages of heat, induced therein by increments of resistance to a current of electricity so varying in character as to yield successively products of progressively increasing carbon content; 5% of coke is added to the mixture of wood or sawdust and lime to reduce the initial resistance. The volatile products (methyl alcohol, acetone, acetic acid, tar) are condensed, and the temperature is then raised so as to convert the residue into calcium carbide. (B) The apparatus comprises a receptacle and electrodes therein, with means for bringing the electrodes and receptacle into an electrical circuit. A non-magnetic armature is adapted to be acted upon by an alternating current for repelling it, and means, governed by the temperature, are provided for regulating the movement of the armature, the latter controlling the operative distance of the electrodes when in use; means are also provided for reversing the movement of the electrodes while communicating with the controlling member.—B. N.

Air and gases; Process for treating — in the electric arc. K. Friedrich. G.P. 300,722, 25.1.16.

In conjunction with a vertical, inverted electric arc, an annular slotted device is arranged horizontally, or in a slightly inclined position, at the lowest point, through which gases, after being heated by the arc, are drawn and thus produce an electric disc-shaped light.—W. J. W.

Electrodes and carbon rods; Furnace for baking —. F. K. Meiser. G.P. 323,797, 25.9.17.

A DEVICE for collecting tar vapours is placed on the saggars. If this receiver is put on the furnace walls instead of on the saggars leakages are unavoidable.—W. J. W.

Electrodes and similar materials; Tunnel furnace for —. F. K. Meiser. G.P. 323,798, 28.2.18.

Is a furnace for the manufacture of electrodes the containers for the electrodes and the cars carrying them are provided below with outlets for vapours evolved, which outlets can be connected with a condensing and collecting system.—W. J. W.

XII.—FATS; OILS; WAXES.

Fats; Catalytic reduction of unsaturated —. A. S. Koss. Przemysl Chem., 1920, 4, 39—48. Chem. Zentr., 1920, 91, IV., 442.

THE catalytic activity of the oxides of nickel in the hydrogenation of oils at 255°—260° C. (cf. Bedford and Erdmann, J., 1913, 611) depends on the method

used to prepare them. Addition of nickel monoxide to the sesquioxide does not always increase the activity of the latter (cf. loc. cit.). The particular combination most suitable for the treatment of any given oil must be ascertained by experiment. Nickel sesquioxide loses its activity on heating in the air, even at 115° C. Its activity is considerably increased by very small quantities of platinum, and this fact may account for some of the results obtained by Bedford and Erdmann. The resistance of drying oils to catalytic reduction is due to the position of the double linkages in the linolenic acid molecule. Those between the 9th and 10th and the 12th and 13th carbon atoms are readily reduced, whilst that between the 15th and 16th is only very slowly attacked. The partially reduced oil therefore remains liquid owing to the formation of a liquid oleic acid. Ordinary oleic acid is readily reduced and possesses no drying properties. The drying properties of linolic acid are due to the double linkage between the 12th and 13th carbon atoms. The further a double linkage is from the carboxyl group the more difficult is it to reduce and the greater is the tendency to polymerisation. These differences in the behaviour of double linkages are well shown by means of a weak catalyst like nickel sesquioxide.—J. H. L.

Fatty oils; Polymerisation of —. J. Marcussen. Z. angew. Chem., 1920, 33, 231—232, 234—235.

OILS thickened by blowing followed by electrical treatment (F.P. 440,843; J., 1910, 222) are sold under the name of "Voltol" oils. The apparatus consists of a horizontal drum which is rotated on an axis upon which is a series of alternate metal and glass discs spaced a few mm. apart. The metal discs are connected with a source of electricity, and a current of about 8 to 10 kw. is passed through the blown oil at a reduced pressure (0.1 atm. or less). Samples of rape and marine animal oils thickened by this process had the following characters:—

	Sp. gr. 15° C.	n_D^{15}	Viscosity at 100° C.	Acid value.	Iodine value.	Mole- cular weight.
Thickened rape oil	0.9740	1.485	83.6	11.7	52	1200
Thickened marine animal oil	0.9819	1.485	74.9	15.4	51	1000

The high viscosity is due to the formation of oxidation products and to intramolecular polymerisation. Polymerisation of oils may also be effected by heating with aluminium chloride or iron chloride. For example, 10 g. of linseed oil is dissolved in 40 c.c. of benzene, and the solution treated gradually with 3 g. of aluminium chloride. In one experiment the viscous product had acid value 15.6, saponif. value 185, and iodine value 120. Toluene, xylene, naphthalene, anthracene, anisol, etc. may be used in place of benzene. Polymerisation of sterols as well as of glycerides takes place in the treatment of oils with aluminium chloride. Oil separated from the yeast *Endomyces vernalis*, after drying in presence of sodium chloride, was found to be polymerised; it had the following characters:—Acid value, 50; saponif. value, 196; and iodine value, 92.—C. A. M.

Iodine value of fats; Comparison of methods for the determination of the —. W. Devrient. Ber. deuts. pharm. Ges., 1920, 30, 361—366.

THE iodine value of elaidic acid, as determined by different methods, was found to be as follows:—Hübl, 80.3; Waller, 80.0; Winkler, 80.8; Wijs, 80.8; Hanus, 82.5. The Hanus method is considered to be

the most rapid and simple, and the result obtained is nearer the theoretical value (90) than are those obtained by the other methods.—W. P. S.

Gelatin as emulsifying agent. Holmes and Child. See 11A.

PATENTS.

Catalysts used in hydrogenation; Revivifying spent —. H. Schlinck und Co. A.-G. G.P. 324,580, 22.1.16.

THE catalyst is boiled with sufficient or less than sufficient acid to dissolve the metal, an alkali or alkali carbonate is added to precipitate the dissolved metal, and the precipitate, after separation from the solution by filtration, is washed and reduced by heating in a current of hydrogen; the temperature is allowed to rise at a rate not greater than 150° C. per hr., so that in 4—5 hrs. it reaches 650° C., at which point the heating is stopped.

—L. A. C.

Yeast masses; Extraction of fat from —. Kriegsausschuss für pflanzliche u. tierische Öle und Fette, G.m.b.H. G.P. 309,266, 31.1.18.

BEFORE extraction with solvents the yeast masses are allowed to undergo autodigestion, whereby the fat globules within the cells are liberated.—J. H. L.

Aluminium hydroxide; Washing and cleaning by means of —. M. Buchner. G.P. 323,193, 21.4.15.

THE material to be washed is treated with water containing aluminium hydroxide in the form of a gel, produced by adding ammonia to solutions of aluminium salts of medium concentration, e.g., 1—5%. The precipitates so formed are highly dispersive, but can be readily filtered and washed.

—J. H. L.

Bile soaps and detergents; Production of —. C. H. Boehringer Sohn. G.P. 323,804, 22.11.18.

ALKALI salts of hydrolysed bile acids, or their components separately, are added to a soap. Apart from their cleansing action, the products soften the fibres of the materials to be washed, without injuring them, and lessen the injurious action of inferior detergents.—J. H. L.

Glycerin substitute [from lactates]. Chem. Fabr. vorm. Goldenberg Geromont und Co. G.P. 303,991, 8.2.16.

AQUEOUS solutions of alkali lactates may be used in place of glycerol for many purposes, e.g., lubrication of machinery, softening of leather, etc. An 80% solution of sodium lactate boils at 126° C., and loses no water by evaporation at the ordinary temperature; a 50% solution does not freeze at -60° C.—J. H. L.

Glycerol; Production of pure — from liquids containing glycerol or from crude glycerol. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 323,666, 14.2.19.

THE impurities are caused to separate in a flocculent form by addition of soluble silicates, preferably water-glass, with the aid of heat if necessary. Heating may be continued until a "crystallisation skin" forms on the surface of the liquid. The products may afterwards be purified by means of milk of lime or barium carbonate.—J. H. L.

Hydrogenating fatty acids and their glycerides; Method of and apparatus for —. A. Radisson (Assr. to Soc. de Stearinerie et Savonnerie de Lyon) and P. Berthou. U.S.P. 1,353,419, 21.9.20. Appl. 21.6.17.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

White lead; "Porcelain" —. E. Euston. J. Ind. Eng. Chem., 1920, 12, 974—975.

THE hardness of the porcelain-like crust formed in the stack process of corrosion for the manufacture of white lead is due, not to its being a definite compound, $2\text{PbCO}_3 \cdot \text{Pb}(\text{OH})_2$, as commonly assumed, but to the cementing effect of the colloidal basic lead acetate present in the formation of the crust. If, in the precipitation process, the compound, $2\text{PbCO}_3 \cdot \text{Pb}(\text{OH})_2$, is dried without previous washing, the degree of hardness of the mass is proportional to the concentration of the basic lead acetate; if thoroughly washed before drying a friable mass is obtained.—C. A. M.

Linoleum; Maturing of —. F. Fritz. Kunststoffe, 1919, 9, 253. Chem.-Zeit., 1920, 44, Rep., 227.

THE relationship between the time, T, necessary for the maturing of linoleum and the thickness, d (in mm.) of the material, is given approximately by the formula: $T = k \cdot d \cdot (d + 2) / 8$; the coefficient, k, for Walton goods lies between 10 and 12. The formula holds good up to considerable thicknesses such as 6.25 mm., but its application is restricted to homogeneous "through to the back" linoleums. Thick materials are commonly removed too early from the maturing rooms. Penetration of air into the linoleum is not the only factor to be considered; the gaseous products formed must also have easy egress. The influence of moisture is also an important factor; the air of the maturing room must be capable of carrying off moisture, a condition which does not often obtain with warm moist air. A deep-seated change is brought about by addition of drier to the mix. Hardening substances, such as the oxides of calcium, barium, magnesium, and zinc, produce an apparently matured linoleum in a shorter time, the hardness subsequently increasing with time. The action of light has no essential influence.—A. de W.

Zinc sulphide. Tiede and Schleede. See VII.

Polymerisation of oils. Marcusson. See XII.

Aldehyde-resins. Hammarsten. See XX.

PATENTS.

Gold-coloured sulphurs and vermilions of antimony; Manufacture of —. P. Chaillaux. E.P. 151,422, 1.8.19.

NATURAL antimony sulphide is melted by heating in a closed vessel, and then treated with gaseous sulphur dioxide or hydrogen sulphide or a mixture of these gases; the trisulphide is thereby converted into golden or crimson tetrasulphide and pentasulphide, which are collected as powder in a settling chamber. Instead of introducing sulphur dioxide as such, air or oxygen in suitable quantity may be led into a molten mixture of the natural trisulphide and sulphur.—D. F. T.

Coating material; Water-resistant — and method of making it. G. W. Miles, Assr. to Ross Chemical Co. U.S.P. 1,354,575, 5.10.20. Appl., 10.1.19.

AN oxidised resin is saponified with ammonia and the concentration of the solution subsequently reduced with water at ordinary temperature.

—A. de W.

Ink tablets; Production of —. H. Rosenberg. G.P. 323,138, 21.9.17.

INK powders or powdered colours, pigments, or aniline dyes, are mixed with chemical substances which are very readily soluble or which develop gases on the addition of water. Thus mixtures generating carbon dioxide or hydrogen, or alkali percarbonates, may be used; basic colours may be converted into strongly acid salts or acid colours into strongly basic salts, and the products mixed with a salt of opposite reaction.—D. F. T.

Lithopone fast to light; Production of —. A. Eibner. G.P. 324,646, 19.2.18.

Zinc liquors free from ammonium salts are treated with ammonia until the precipitated zinc hydroxide is just dissolved; after boiling for a short time, granulated zinc is added and the solution kept at the ordinary temperature for 12 hrs. By this treatment any metals which could give rise to a coloured sulphide are removed; these metals are the cause of the lack of fastness of colour in lithopone which is accentuated by the presence of chlorine.—D. F. T.

Resin; Process of producing artificial —. H. N. Copthorne and A. L. Tannehill. U.S.P. 1,353,220, 21.9.20. Appl., 5.6.19.

A SOLUTION of artificial resin is obtained by adding to a solution of the lighter and heavier fractions of the light oil distillates of coal tar, in the absence of water, approximately 1½% of sulphuric acid and afterwards neutralising.—D. F. T.

Linseed oil varnish; Substitute for —. R. Koetschan, C. Harries, and E. Albrecht. G.P. 323,155, 25.3.17.

A SUBSTITUTE for linseed oil varnish is supplied by the ozonides of unsaturated hydrocarbons, particularly of petroleum, or of the tar products derived from lignite, peat, or shale. The ozonides can be used in inert solvents such as benzene or carbon tetrachloride, or in admixture with other varnishes or siccatives. The rate of drying can be increased by previous exposure in shallow vessels; by warming it is possible to cause partial decomposition of the ozonides with the formation of peroxides, thereby producing a varnish of different capacity for drying.—D. F. T.

Indurated compounds from lac or its derivatives; Process for producing —. W. W. Simonson and L. Van D. Blair. E.P. 127,825, 2.6.19. Conv., 1.6.18.

SEE U.S.P. 1,309,967 of 1919; J., 1919, 648 A. (Reference is directed, in pursuance of Sect. 7, Subsect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 16,800 of 1904.)

Paint or varnish; Manufacture of —. Koppers Co., Assees. of M. Darrin. E.P. 129,264, 12.6.19. Conv., 29.6.18.

SEE U.S.P. 1,296,776 of 1919; J., 1919, 379 A.

Resin; Manufacture of —. Koppers Co., Assees. of M. Darrin. E.P. 132,229, 24.6.19. Conv., 6.9.18. SEE U.S.P. 1,297,328 of 1919; J., 1919, 428 A.

SEE U.S.P. 1,321,708 of 1919; J., 1920, 13 A.

Paints; Manufacture of —. J. E. Schneider. E.P. 151,687, 19.6.19.

SEE U.S.P. 1,317,225 of 1919; J., 1919, 916 A. (Reference is directed, in pursuance of Sect. 7, Subsect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 1432 of 1883, 15,363 of 1886, 9480 of 1905, and 25,266 of 1909.)

Paint or composition for covering the surface of metals and other materials. C. H. Iverson and G. S. Roberts. E.P. 151,666, 24.9.19.

Resinous product. U.S.P. 1,355,103. See 111.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanised rubber; Effect of certain accelerators upon the properties of —. G. D. Kratz and A. H. Flower. J. Ind. Eng. Chem., 1920, 12, 971–974.

As a result of vulcanisation tests of extracted and unextracted rubber in presence of light magnesia, it is concluded that the action of small amounts of magnesia in accelerating the vulcanisation of rubber is, to a large extent, of a secondary character, and depends upon its netting in conjunction with certain extraneous substances (probably nitrogenous) present in the rubber. The activity of the magnesia as accelerator depends upon the nature and quantities of these substances. (Cf. J., 1919, 781 A.)—C. A. M.

Rubber; Determination of factice in —. P. Dekker. Gummi-Zeit., 1920, 35, 52–55.

ON account of the resistance of rubber to penetration by alcoholic alkali hydroxide, the customary procedure for the estimation of fatty "rubber substitute" ("factice") tends to give low results. The following method is recommended:—2 g. of the rubber, after extraction with acetone, is steeped overnight in 20 c.c. of benzene; 40 c.c. of N/2 alcoholic potassium hydroxide is added, and the mixture is boiled under a reflux condenser for 4 hrs.; the liquid is filtered, the residue washed successively with boiling alcohol and boiling water, and the combined filtrates evaporated to a bulk of 3–5 c.c.; the fatty acids in this liquid are then estimated in the usual way. The presence of asphaltum in the rubber interferes with the accuracy of the factice determination, the results being too high. Oxidation of the rubber due to prolonged exposure of the sample between the acetone extraction and the subsequent hydrolysis also gives rise to inflated values for the factice content. In an editorial note it is stated that the addition of the alcoholic alkali to the mixture of rubber and benzene should be effected with both liquids at the boiling temperature.—D. F. T.

PATENTS.

Rubber; Treatment of raw — when freshly coagulated from the latex. S. C. Davidson. E.P. 151,344, 20.6.19.

FRESHLY obtained rubber coagulum ordinarily contains a large proportion of water partly enclosed mechanically. The sheets of coagulum are therefore finely perforated by pins mounted in a board; the perforations act as drainage tubes and facilitate the escape of inclusions of gas or water. The rubber is then rolled into thin sheets and finished in any desired way without the necessity of maceration.—D. F. T.

Vulcanised artificial rubbers; Process for increasing the elasticity of —. Farbenfabriken vorm. F. Bayer und Co. G.P. 301,757, 28.12.15.

PRIOR to vulcanisation, 10% or more of an oily substance, such as petroleum, linseed oil, castor oil, paraffin oil, hemp seed oil, safrole, aniline, the alkylanilines, xylydine, and dimethyl-*p*-toluidine, is introduced into the mixture.—D. F. T.

Rubbers, gutta-percha, balala, etc.; Improvement of the plasticity and adhesiveness of difficultly soluble natural —. Ungarische Gummiwaarenfabriks-A.-G. G.P. 323,732, 21.3.18. Conv., 4.5.17.

MATERIALS of the above type are heated with a

rubber solvent such as petroleum naphtha or benzene, phenol, aniline or their homologues, the solvent being subsequently removed. The products are easily soluble, plastic, adhesive, and capable of absorbing the usual compounding ingredients.

—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Chrome [tanning] liquors; Effect of neutral salts on the basicity of —. B. B. Dhavale and S. R. Das. *J. Soc. Leather Trades' Chem.*, 1920, 4, 225—230.

THE end point in the alkalimetric titration of chrome liquors for acidity by the Procter and McCandlish method was found to be influenced by the temperature at which the titration was done and the rate at which the alkali was added, but the dilution of the liquor under titration did not exert any influence. Additions of sodium chloride caused a marked increase in the acidity as determined by this method.—D. W.

Sulphide [in tannery lime liquors]; Estimation of —. Committee of the Soc. of Leather Trades' Chemists on Limeyard Control. III. J. E. Pickles. *J. Soc. Leather Trades' Chem.*, 1920, 4, 231—235.

SOLUTIONS of commercial sodium sulphide are precipitated with cadmium acetate solution; lime liquors containing sulphide are decomposed with acid and the hydrogen sulphide thus liberated distilled into cadmium acetate solution. In either case the cadmium sulphide is filtered off, treated with a known excess of N/20 iodine solution, and the excess titrated with N/20 sodium thiosulphate. 1 c.c. N/20 iodine is equivalent to 0.00085 g. H_2S or 0.00195 g. Na_2S .—D. W.

[Tannery] lime liquors; Caustic alkalinity of —. Committee on Limeyard Control. IV. W. R. and J. Atkin. *J. Soc. Leather Trades' Chem.*, 1920, 4, 236—243.

AT $pH=10.0$ only 24% of the ammonia present in a solution is neutralised. A sample of the lime liquor is titrated with standard acid to the value $pH=10$, using the comparator (J., 1920, 605 A) and thymolphthalein as indicator. This titration is a measure of the caustic alkalinity plus 24% of the ammonia but does not cause any decomposition of the sulphide present. The ammonia is determined by distillation, and the caustic alkalinity then calculated.—D. W.

Gelatins and glues; Jelly strength of —. S. E. Sheppard, S. S. Sweet, and J. W. Scott, jun. *J. Ind. Eng. Chem.*, 1920, 12, 1007—1011.

A TORSION dynamometer is described for determining the jelly-strength of glues and gelatins when moulded into cylindrical test pieces. The product of the breaking load multiplied by the percentage twist at breaking point, divided by the cross section of the test piece is taken as the jelly strength. No simple relationship could be established between the concentration of gelatin and the jelly strength, nor between the jelly strength at a given concentration and the tensile strength of a dry glue joint.

—C. A. M.

Gelatin as emulsifying agent. Holmes and Child. See 11A.

PATENTS.

Glue solutions; Apparatus for the concentration of —. Goslar-Apparetebau Samstag und Co. G.P. 323,845, 28.8.17.

THE glue solution trickles on to a whirling plate, which distributes the liquid in fine drops on to the

corrugated walls of the apparatus down which it flows, meeting an upward current of warm air.

Liming of hides [; Means for circulating the liquor in —]. H. Boston and Sons, Ltd., and J. L. Fairrie. E.P. 151,387, 3.7.19.

Adhesives. G.P. 323,665 and 324,928. See XVII.

XVI.—SOILS; FERTILISERS.

Plant analysis and manuring. F. Münter. *J. Landw.*, 1920, 68, 207—224.

EXPERIMENTS were made during five years upon the growth of barley and sugar beet in a loam soil fertilised with stable manure, nitrate, potash salts, and phosphate, separately and in combination. Results showed that the calcium and magnesium content of barley were little affected, but the silica of the straw was decreased by nitrogen and phosphate applications to the soil. The nitrogen content was raised by potash and phosphate. The weather factor had so much effect that no other definite deductions could be drawn. Analysis showed that the roots of sugar beets were little affected by manuring, whereas calcium and magnesium in the tops were increased by potash manuring and decreased by phosphate. In the case of beet also, weather variations influenced growth so strongly that no deductions could be drawn from plant analysis as to the needs of the soil for particular manures. For this last purpose, two differently manured plots must be compared, one fertilised with nitrogen, and the other with potash and phosphate. Under these conditions the following general statements may be made:—If, on the nitrogen plot, the ratio of nitrogen to potash is greater than unity, the soil is deficient in potash; if, on the same plot, the ratio of nitrogen to phosphate is greater than 100:20, the soil is deficient in phosphate; while if, on the phosphate and potash plot, the latter ratio is less than 100:35, the soil is deficient in nitrogen.—J. H. J.

Calcium and iron salts; Antagonistic action of — towards other salts as measured by ammonification and nitrification. J. E. Greaves. *Soil Sci.*, 1920, 10, 77—102.

EXPERIMENTS were made on the effect produced on the bacterial activity of a fertile loam soil by the addition of calcium and iron salts. The ammonifying and nitrifying powers of the soil were first reduced by the addition of various salts, then increasing amounts of the calcium salt or the iron salt were added, and the effect on ammonification and nitrification was observed. Calcium sulphate was found to neutralise the toxic effect on ammonification of sodium carbonate, nitrate, and sulphate, calcium chloride, and magnesium chloride and sulphate. It had no antagonism to sodium chloride. Similar results were obtained in the case of nitrification, except that there was no antagonism towards sodium sulphate and calcium chloride. Thus both the anion and cation take part in the antagonism. Ferrous sulphate was antagonistic to sodium sulphate, chloride, carbonate, and nitrate, and to calcium chloride; ferrous chloride to sodium chloride and nitrate, calcium chloride and magnesium sulphate; ferrous nitrate to magnesium chloride and sulphate, calcium chloride and sodium carbonate, sulphate, chloride, and nitrate; ferrous carbonate to sodium chloride and carbonate, calcium chloride, and magnesium sulphate. The greatest effect was produced by ferrous carbonate on magnesium sulphate. 75% of the toxic effect of the latter being neutralised. In the case of nitrification the action of the iron salts varied somewhat from that on ammonification, the greatest effect

being produced by ferrous nitrate on magnesium chlorido. The amount of iron required to produce the maximum effect varied with the different salts, but in no case exceeded 186 parts per million.

PATENTS.

Calcium cyanamide; Process of granulating — for use as a fertiliser. P. M. T. Savès. E.P. 135,847, 25.11.19. Conv., 26.11.18.

To produce calcium cyanamide in a granular condition it is treated with a solution of a silicate, preferably potassium silicate, during its hydration for removal of calcium carbide. The resulting paste is kneaded, dried, and crushed. Phosphorus-containing materials such as bone ash or slag may be incorporated with the product.—W. J. W.

Fertilisers. J. R. Partington and L. H. Parker. E.P. 151,024, 26.6.18.

AMMONIUM nitrate in the form of a dry powder is mixed with bone meal, and the mixture is finely ground. Suitable proportions are ammonium nitrate 1 pt., and bone meal 3 pts. Potassium salts or other fertilising materials may be added. The fertiliser is said to keep dry, and free from caking, on exposure to the atmosphere.—W. J. W.

Plants; [Use of radio-active composition in] growing —. E. Miller. U.S.P. 1,353,931, 28.9.20. Appl., 29.6.18. Renewed 12.8.20.

CARBE carnotite ore tailings is heated, ground, and mixed with inert material to form a radioactive composition for stimulating plant growth.—W. J. W.

Parasites; Process for destroying — and increasing the germinating power of seeds. A. Traube. G.P. 323,925, 3.18.19.

SRLPHUR, dissolved in pyridine or in substances containing it or its homologues, with or without addition of water, is effective for destroying animal or vegetable parasites and for stimulating the germination of seeds.—W. J. W.

Fertilisers; Process for the manufacture of —. A. C. Bohre; K. C. Bohre, extrix. U.S.P. 1,351,719, 5.10.20. Appl., 13.8.19.

SEE E.P. 132,496 of 1919; J., 1920, 311 A.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose; Destruction of — during the boiling of low-grade massecuites. H. L. White. Int. Sugar J., 1920, 22, 588.

On boiling first massecuites at 140°–145° F. (60°–63° C.) figures were obtained leading the author to conclude that under the conditions obtaining generally in Hawaii no appreciable loss of sugar occurs; whereas at the higher temperature of 165°–172° F. (74°–78° C.) there may be a considerable loss.—J. P. O.

Sucrose; Loss of — by inversion during the heating of second massecuites and final molasses. R. C. Pitcairn. Int. Sugar J., 1920, 22, 589.

RESULTS were obtained indicating that there is a very decided danger of inversion while boiling the low-grade products if they are not kept nearly neutral. A massecuite having an acidity corresponding to 0.25% CaO may lose sugar by inversion during boiling, but in the case of molasses, owing to its lower purity, the risk is less. The diminution

of the sucrose content that may occur in this way is capable of reaching an important degree, and probably accounts for a proportion of the unknown losses.—J. P. O.

Decolorising blacks [for sugar refining]. C. F. Bardorf. Canad. Chem. J., 1920, 4, 207–211.

CHARRED sawdust, though destitute of decolorising power, greatly facilitates the filtration and handling of dusty and sooty chars when mixed therewith, and also increases their efficiency by acting as a dispersive medium and preventing agglomeration. Very satisfactory results were obtained by mixing it with prepared carbon from decomposed char dust or even with ground discarded refinery char. On these lines a new product, "Karhos," has been prepared as follows:—1 kg. of 100-mesh char dust is digested with 1250 c.c. of hydrochloric acid of 18° B. (sp. gr. 1.11) for 20 hrs. The pasty mass is mixed with 23 l. of water and 70 g. of charred sawdust, and the mixture is agitated and filtered rapidly; the filtrate, containing phosphates, may be used as a defecating agent or evaporated and sold as superphosphate. The resulting char is washed twice with 23 l. of water, the first washing being afterwards used to dilute a later batch of paste, whilst the second washing is discarded. The char thus obtained filters excellently, and can be partially dried by pumping warm air through the filter press. Addition of 30–50% of charred sawdust to "Eponite" was found to increase the decolorising efficiency of the latter in the mixture by about 25%.—J. H. L.

Sucrose; Determination of — in presence of both invert sugar and raffinose. W. Montgomery. Int. Sugar J., 1920, 22, 580–582.

TABLES are given by aid of which a "sucrose factor" and a "raffinose factor" can be calculated from the amount of reduced copper for use in estimating sucrose, invert sugar, and raffinose in mixtures by a combined method involving polarimetric and cupric-reducing determinations.

Carbohydrate economy of cacti. [Determination of pentose sugars.] H. A. Spoehr. Publ. No. 287, Carnegie Inst. of Washington, 36–37.

IN determining the pentose sugars in cacti extracts, in preference to employing Tollens' furfural method, the accompanying hexoses were eliminated by fermentation, the alcohol removed by distillation, and the cupric-reducing power of the residue determined (using the iodide volumetric method after separating the cuprous oxide by centrifuging), the absence of other non-fermentable sugars having been previously established.—J. P. O.

PATENTS.

Adhesives [gum substitutes]; Production of —. H. Wallasch. G.P. 323,665, 20.4.19.

By the condensation of formaldehyde with dicyanodiamide in the presence of sulphuric acid adhesive products are obtained; with 1 pt. of dicyanodiamide to 2 pts. of 30% formaldehyde solution a fluid product is obtained resembling gum arabic, whilst with a lower proportion of formaldehyde the product is more viscous.—D. F. T.

Adhesives (not sizes for paper); Production of — from lignite. H. S. Gerdes. G.P. 324,928, 27.3.18.

By treating finely divided lignite, which has been saturated with water, with caustic alkali a colloidal suspension and a thick deposit are obtainable. These can be dried separately or together and used for adhesive purposes.—D. F. T.

Nutrient yeast. G. P. 314,601. See XIX A.

XVIII.—FERMENTATION INDUSTRIES.

Diatase enzymes; Influence of neutral alkali salts on —. A. Hahn and K. Harpuder. *Z. Biol.*, 1920, 71, 287.

THE optimum hydrogen ion concentration for the activity of ptyalin is $p_H = 6.4-6.5$, for that of malt diastase $p_H 4.7$. = The enzymic activity is not only influenced by the hydrogen ion concentration of the buffer substances present, but by the concentration of the other ions contained in them. The combination of neutral alkali salts with the buffer substances produces either an accelerating or an inhibiting influence, according to the reaction and the concentration of the salts and buffer substances, on the activity of the enzymes. The optimum hydrogen ion concentration is also changed by the combined influence of the neutral salts and the buffer substances. Neutral alkali salts displace the isoelectric point of ptyalin and malt diastase in the acid direction. The influence of sodium salts is more marked than that of potassium salts. The mode of action of the above enzymes is independent of their electrical nature.—S. S. Z.

Maltase solutions from yeast. R. Willstätter, F. Oppenheimer, and W. Steibelt. *Z. physiol. Chem.*, 1920, 110, 232-241.

MALTASE can be obtained from fresh beer yeast previously killed by an antiseptic, such as chloroform or toluene, by extracting it with water in the presence of ammonia. The authors suggest that, owing to some enzymic process, acid is formed in the yeast cell, which is responsible for the destruction of the maltase when it is extracted from the undried cell, and that the neutralising effect of the ammonia makes it possible to obtain the enzyme also from the fresh yeast cell. The relation between the concentration of the enzyme and the decomposition of maltose, as well as the velocity of the reaction, was studied with maltase preparations from dried and fresh yeasts. The activity of maltase solution is impaired by treatment with kaolin.—S. S. Z.

Acetone and butyl alcohol fermentation of starch; Gas production during —. H. B. Speakman. *J. Biol. Chem.*, 1920, 43, 401-411.

THE following scheme is put forward to represent the course of the fermentation:—

- (1) $(C_6H_{10}O_5)_x + xH_2O = xC_6H_{12}O_6$.
(starch) (dextrose)
- (2) $C_6H_{12}O_6 = C_3H_7CO_2H + CH_3CO_2H + [O_2]$.
- (3) $2C_3H_7CO_2H + O_2 = 2CH_3CO_2CH_2COOH + 2H_2$.
- (4) $CH_3CO_2CH_2COOH = CH_3CO_2CH_3 + CO_2$.
- (5) $C_3H_7CO_2H + 2H_2 = CH_3(CH_2)_2OH + H_2O$.
- (6) $CH_3CO_2H + 2H_2 = CH_3CH_2OH + H_2O$.

This scheme satisfactorily explains the formation of the substances produced, but one or two points still require elucidation before the process is completely understood. (*Cf.* J.C.S., i., 797.)—J. C. D.

Jerusalem artichokes; Working of — in the distillery. K. Windisch. *Z. Spiritusind.*, 1920, 43, 292, 300.

IN laboratory experiments with artichokes gathered in the early part of the year, yields of alcohol ranging from 7 to 10 l. per 100 kg. of tubers were obtained by fermenting a mash of the pulped material with beer yeast (*cf.* Rüdiger, J., 1920, 608A). Preliminary steaming of the pulp at atmospheric or higher pressures reduced the yield of alcohol, and no advantage accrued from the addition of malt to the mash. For small distilleries the following procedure is recommended: The washed tubers are finely pulped, introduced into the fermenting vat, and treated with sufficient water to produce a somewhat fluid mash. Hot water may

be added at first to sterilise the pulp as far as possible, and then cold water. The mash is pitched with 0.5 kg. of pressed yeast per 100 kg. of artichokes, and the fermentation temperature should approach but not exceed 30° C.—J. H. L.

Iodoform reaction. Kunz. *See* XX.

PATENTS.

Malt; Reducing the amount of — used for the saccharification of amylaceous mashes. A. Deutschland. G.P. 323,653, 5.4.19.

THE addition of killed yeast, autolysed yeast, or yeast extract to amylaceous mashes enables saccharification to be effected with less than the usual quantity of diastase or malt. Yeast extract may be produced in the mash itself before the addition of the malt, by heating the mash to 80° C. and adding fresh yeast.—J. H. L.

Mashes and beer worts; Boiling of — under pressure. Nathan-Institut A.-G. G.P. 323,707, 30.3.17.

IN a process of boiling under pressure in which the vapours evolved are conducted away from the liquid, the intensity and duration of boiling are so increased as to remove all the volatile flavouring and aromatic substances and to render permanently soluble the constituents which have become soluble under pressure.—J. H. L.

Spanish moss. U.S.P. 1,327,873. *See* V.

XIXA.—FOODS.

Histidine; Estimation of — in protein and protein-containing matter. M. T. Hanke and K. K. Koessler. *J. Biol. Chem.*, 1920, 43, 527-542.

THE diamino-acids are precipitated from the hydrolysed protein by means of phosphotungstic acid, and the histidine in this precipitate is estimated by means of the colorimetric method previously described (Koessler and Hanke, J., 1919, 962A). (*Cf.* J.C.S., Dec.)—J. C. D.

Histamine; Colorimetric method for estimation of — in protein and protein-containing matter. M. T. Hanke and K. K. Koessler. *J. Biol. Chem.*, 1920, 43, 543-556.

A DESCRIPTION of a long process which aims at isolating histamine in a more or less pure condition before applying the colour test previously described (Koessler and Hanke, J., 1919, 962A). The method is accurate in the estimation of minute quantities of the amine. Histamine was not found present in caseinogen or human blood serum. (*Cf.* J.C.S., Dec.)—J. C. D.

PATENTS.

Drying tea or like vegetable or other substances; Apparatus for —. H. A. Tempelaar. E.P. 151,461, 12.9.19.

IN a chamber through which an upward current of warm air is passed, a number of circular rotary drying surfaces are mounted one above the other on a central shaft and so geared that each rotates in a direction opposite to that of the next one. The drying surfaces consist of circular frames supporting segmental tray sections each of which is tilted about a radial axis, once in every revolution, by engaging a fixed projection from the casing. The material is first distributed over the top drying surface and, by the successive tilting of the sectional trays, discharged on to the surface next below, and so on.—J. H. L.

Drying [fish etc.]; Chambers for —. P. Fleury and D. L. Robertson. E.P. 151,488, 20.10.19.

PERFORATED trays to hold the material to be dried are arranged within a closed chamber through which heated air is drawn by fans carried by a rotating central shaft and arranged above and below the trays. A perforated distributing plate is provided at the bottom of the chamber, and below this is a chamber opening laterally to the atmosphere and containing a steam heating coil. A blower mounted at the upper end of the central shaft controls the passage of the heated air through the chamber.—J. S. G. T.

Food; Manufacture of animal — from kitchen waste and the like. R. L. D. Taylor, Assr. to Predigest Food Co., Ltd. U.S.P. 1,354,068, 28.9.20. Appl., 25.2.19.

GARBAGE is pulped, dried in motion so as to form nodules, cooked without breaking up the latter, and finally screened to separate the nodules from the coarser and finer fractions; or the garbage is mixed with a pulverulent absorbent vegetable filler, and the partly dried mixture is pulped and then dried in motion at a temperature above 300° F. (150° C.) so as to form nodules.—J. H. L.

Fire-gases from a coke or coal fire; Apparatus for obtaining — free from smell, soot, and dust, for drying vegetable and animal foodstuffs. O. Breidenbach. G.P. 319,777, 23.9.17.

The gas stream is divided into a number of horizontal streams to which air is admitted to ensure complete combustion of the gas. The velocity of the gas is increased towards the end of the horizontal course, the separate streams then unite, and the combined stream passes sharply downwards, whereby a portion of the fine dust settles out. The gas stream flows again in a horizontal course, and passes over means for precipitating the ash, turns sharply upwards, and the last traces of dust and soot are removed in a double filter-sieve against a counter-current of fresh air.—L. A. C.

Yeast; Production of nutrient — especially for use as nitrogenous fodder, from waste waters of sugar factories. A. Riedel. G.P. 314,601, 16.2.18.

TUZ diffusion process is carried out with ammoniacal "fall water" and condensed water from the evaporating plant, and the waste diffusion and press waters are mixed with yeast, without aeration, the solids being subsequently separated and dried.—J. H. L.

Potato products; Preparation of dried —. Chem. Ges. Rhenania m.b.H. G.P. 322,821, 17.9.18. Addn. to 312,614 (J., 1919, 842 A).

BEFORE being dried, the sliced potatoes are treated with an electrolysed sodium chloride solution containing 120 g. of active chlorine per 100 kg. of potatoes. No free chlorine remains in the potatoes after drying, and the latter retain their original colour.—J. H. L.

Bones; Utilisation of — with production of an edible fat and a valuable fodder. J. Brix. G.P. 323,650, 23.6.16.

FRESH bones are boiled, first under a low pressure, up to 2 atm., and then under a higher pressure. The liquors obtained from the two operations are separately freed from fat, and the liquor from the first boiling is then concentrated and mixed with the bone residues after the latter have been comminuted.—J. H. L.

Fodder from straw; Manufacture of —. E. Beckmann, and Veredelungsges. für Nahrungs- u. Futter-Mittel. E.P. 151,229, 15.8.19. Conv., 25.4.17.

SEE G.P. 305,641 of 1917; J., 1919, 789 A.

XIXB.—WATER PURIFICATION; SANITATION.

Ammonia nitrites, and nitrates [in water]; Colorimetric estimation of —. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 1253—1264.

THE effects of time, temperature, quantity of reagent, presence of retarding substances, etc., on the colorimetric determinations in water analysis are examined, and several modifications suggested. In the ammonia determination, Winkler's reagent is found unsatisfactory, and nephelometric estimation by means of alkaline mercury-sodium chloride, which gives a white opalescence with 0.1 mg. NH_4 per l., is proposed instead. Modifications of the phenol-sulphuric acid method for determination of nitrate and of the Griess-Romijn method for nitrites are also put forward. (Cf. J.C.S., ii., 703.) —S. I. L.

X-ray fluorescence of certain organic [and inorganic] compounds. H. S. Newcomer. J. Amer. Chem. Soc., 1920, 42, 1997—2007.

SEVERAL inorganic salts, 308 organic compounds apart from dyes, and 157 dyes have been treated with powerful X-rays with the object of finding a substance, soluble in water, which will transform these rays into bactericidally active ultra-violet rays. A large number of the substances become fluorescent under the treatment, but only sodium bromide gives rays of the desired nature. (Cf. J.C.S., Dec.)—J. F. S.

PATENTS.

Purification of expired air; Process for —. M. Speter. G.P. 323,210, 1.7.19.

FOR the purification of vitiated air, use is made of alkali peroxides which are first fused, and then incorporated after solidification with inorganic compounds of high melting point which do not interact with them, such as chlorides, sulphates, carbonates, and phosphates. The efficiency of the product is increased by addition of catalysts such as manganese dioxide.—W. J. W.

Sulphite - waste - liquor preparation. U.S.P. 1,327,862. See V.

Destroying parasites. G.P. 323,925. See XVI.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine in opium; Determination of —. A. Jernstad. Inaug. Dissert., Basle, 1920, 1—151. Chem.-Zeit., 1920, 44, Rep., 235.

THE only methods of practical importance for the estimation of morphine in opium are the water extraction and the lime extraction methods. The lime extraction methods of the American, English, French, Japanese, Dutch, and Spanish Pharmacopœias yield impure morphine and generally too high results. If, however, the morphine is freed from narcotine and calcium meconate by means of benzene and alcohol, the results coincide with those obtained by the Helfenberger water extraction method. Of the unofficial water methods only those of Dieterich (simplified Helfenberger method), Frey and Thoms are of value. The methods of Hauke and of Léger and Picard give too low, and that of Merck too high results. Of the unofficial lime extraction methods examined, only Beckurt's is usable, those of Asher, Carles, Debouredaux, Guérin, Hager, Maske, and Petit and Picard give impure morphine, some results being too high and others too low. In the Helfenberger method the use of ethyl acetate has no advantage over ether, but methyl red is preferable to iodoquin

indicator. For pharmacopœial use the following modification of the Helffenberger method is recommended:—6 g. of opium is rubbed to a smooth paste with 6 g. of water, and transferred to a weighed flask with water to a total weight of 54 g. After keeping with continual shaking for half an hour, the extract is filtered through a dry 10 cm. filter paper, and to 40 g. of the filtrate is added 2 g. of *N*/1 ammonia, and immediately after mixing the liquor is once more filtered. To 36 g. of the filtrate are added 7 g. of ether and 4 g. of *N*/1 ammonia and the mixture is vigorously shaken in a stoppered flask for 10 mins. A further 10 c.c. of ether is then added and after standing half an hour the ether layer is poured off as completely as possible through a small filter, the operation being repeated with another 10 c.c. of ether. The whole contents of the flask are then poured on to the same filter and the flask with the crystals remaining in it is rinsed out three times with 5 c.c. of water saturated with ether which is finally passed through the filter. The flask and filter paper are then dried at 100° C., and the contents of the latter transferred as completely as possible to the flask and dissolved in 25 c.c. of *N*/10 hydrochloric acid. The solution is then poured through the filter paper to dissolve any crystals remaining on it, and flask and filter are finally washed with 75 c.c. of water. The combined solution and washings are then titrated back with *N*/10 sodium hydroxide with methyl red as indicator. Between 8 and 11 c.c. should be required, corresponding to 10–12% of anhydrous morphine in the opium. (1 c.c. *N*/10 HCl=28.5 mg. of morphine.) For the preparation of *Extractum opii* the following shortened process may be employed:—10 parts of powdered opium is rubbed to a smooth paste with 10 parts of water, 40 parts of water added and after keeping an hour with frequent shaking, the extract is separated and the residue once more treated as above with 25 parts of water. The united extracts are filtered and evaporated to a dry extract.—G. F. M.

Cinchona preparations; Assay of — F. Lehmann. Arch. Pharm., 1920, 258, 85–90.

THE acid extraction of cinchona bark and its preparations indicates a lower alkaloidal content than the extraction from alkaline mixtures. When the alkaloidal extracts from the latter mixtures are subjected to a subsequent purification by being agitated with acid, a portion of the alkaloids is lost in addition to the neutral substances; the alkaloidal content as found by the two processes, however, becomes more nearly identical.—H. W.

Digitalis leaves; Activity of — from one and two year old plants. G. Joachimoglu. Arch. Pharm., 1920, 258, 33–55.

THE activity of the leaves of digitalis plants grown from seeds originating from various districts of Germany decreased rather than increased with the age of the plants, and the pharmacopœial requirement that the leaves should be gathered from two-year old plants appears to require revision. Leaves kept for a year after quickly drying at 60° C. showed no decrease in activity; when dried by the ordinary method a slight decrease was perceptible.—G. F. M.

Chelidonium alkaloids. II. Quantitative determination of dioxymethylene groups in alkaloids. J. Gadamer. Arch. Pharm., 1920, 258, 148–167.

A FULL description of the experimental evidence on which the formula of allocryptopine (Arch. Pharm., 1919, 257, 298) rests is given. Chelerythrine is closely related to homochelidonine. It contains two methoxyl and one dioxymethylene group. The dioxymethylene groups in alkaloids may be approximately determined in the following manner. Pure

phloroglucinol (0.3 g.) is dissolved in a warm mixture of water (15 c.c.) and concentrated sulphuric acid (15 c.c.) and a weighed amount of the alkaloid dissolved in water (5 c.c.) is added. The mixture is shaken until a clear solution results and concentrated sulphuric acid (10 c.c.) is added. The mixture is boiled gently until a precipitate begins to form, after which it is kept at 70°–80° C. for 3 hrs. After 24 hrs. the precipitate is collected in a Gooch crucible, washed with water (60 c.c.), dried at 100° C. for 4 hrs., and weighed. The weight of phloroglucide divided by 9.857 gives the amount of methylene, CH₂. The process should be repeated with varying amounts of alkaloids and occasional blank experiments must be performed. The results are to be regarded as minimal values but are, in general, sufficiently accurate to indicate the number of dioxymethylene groups present. (Cf. J.C.S., Dec.)—H. W.

Chelidonic acid; Occurrence of — E. Stransky. Arch. Pharm., 1920, 258, 56–69.

THE crystalline precipitate obtained by the fractional precipitation of the cold water extract of *Convallaria majalis* by means of lead acetate solution was identified as the lead salt of chelidonic acid, the occurrence of which has previously only been noticed in *Chelidonium majus*, *Veratrum album*, and *Buphone disticha*. As chelidonic acid is quantitatively converted by boiling milk of lime into 1 mol. of acetone and 2 mols. of oxalic acid, this reaction was utilised for the detection and quantitative estimation of the acid in *Convallaria* and numerous other plants. The largest amount found was 2.09–2.18% in the leaves of *Convallaria majalis*. A high percentage, 1.42–1.53, was found in an entirely new source, namely, *Sabadilla* seeds. *Chelidonium majus* contained from 0.14 to 0.74% according to the season and the particular part of the plant. In certain *Veratrum* sp. 0.04–0.39% was found, and traces were indicated in various other Liliaceous and Amaryllidaceous plants.—G. F. M.

Ephedrine and pseudoephedrine; Synthesis of inactive — A. Eberhard. Arch. Pharm., 1920, 258, 97–129.

IMPROVEMENTS in the preparation of α -methylamino-propiophenone from methylamine and α -bromopropiophenone (Eberhard, Arch. Pharm., 1915, 253, 62) and the substitution of hydrogen under pressure in the presence of palladinised charcoal for sodium amalgam in the reduction of the ketone have rendered possible the production of phenyl- α -methylaminoethyl carbinol, C₆H₅CH(OH)CH(NCH₃)₂CH₃, in considerable quantity. A fuller study of this base [B], m.p. 114° C., has revealed the existence of an isomeric base [A], m.p. 76° C., and a number of salts and derivatives of each are described. The inactive synthetic compounds, their salts and derivatives, show great similarity to the natural, optically active bases both in appearance and melting point; this is particularly noticeable in the case of the α -base and pseudoephedrine. The synthetic bases can be converted one into the other in a similar manner to ephedrine and pseudoephedrine; this can be partly effected by hydrochloric acid at the ordinary pressure, but more readily at higher temperature and under increased pressure, whilst the base A is completely converted into base B by acetylation but not by benzoylation. (Cf. J.C.S., Dec.)—H. W.

Sulphonal and trional; Identification of — W. Zimmermann. Apoth.-Zeit., 1920, 35, 27.

THE m. pt. of sulphonal is 125°–126° C., that of trional 76° C. Both substances yield an odour of mercaptan when fused with an equal weight of sodium salicylate; if the mixture is then heated

with alcohol and sulphuric acid an odour of methyl salicylate is observed. When 0.2 g. of sulphonal or trional is mixed with 0.04 g. of sodium salicylate and ignited in a porcelain basin, a violet coloured residue is obtained which yields a violet solution when treated with a drop of water; this colour changes rapidly to brown-red. If the residue is treated with a drop of dilute hydrochloric acid, a yellow solution containing a brown flocculent precipitate is obtained and sulphur dioxide is evolved. When treated similarly, acetanilide, antipyrine, and phenacetin give a black residue, veronal yields a bright yellow residue, and santonin a red residue.

—W. P. S.

Hypnotics; New class of —. *Dialkylhomophthalimides*. A. Lumière and F. Perrin. *Comptes rend.*, 1920, 171, 637–639.

DIETHYL-, ethylpropyl-, dipropyl-, and diallylhomophthalimides may readily be prepared by the action of the corresponding alkyl iodides on homophthalimide in the presence of sodium ethoxide. They are all hypnotics, and at the same time only very slightly toxic and free from any unfavourable secondary action. (*Cf.* J.C.S., i., 780.)—W. G.

Quinoline synthesis; Modification of Skraup's —. E. de B. Barnett. *Chem. News*, 1920, 121, 205–206.

By a modification of Skraup's quinoline synthesis, using the aniline and glycerol in approximately equimolecular proportions, and calcined ferric oxide instead of nitrobenzene or arsenic acid as oxidising agent, yields of 40–50% of the theoretical, calculated on both aniline and glycerol, were obtained. Increasing the proportion of glycerol did not materially improve the yield of quinoline, and it seems probable that the comparatively low yield is due more to the destruction of the aniline by the oxidising agent than to the decomposition of the glycerol. A 60% yield of quinoline was obtained by mixing 50 g. of aniline, 65 g. of glycerol, and 100 g. of ferric oxide, and adding the mixture rapidly to 150 c.c. of concentrated sulphuric acid in an open dish. After standing for half an hour the product is worked up in the usual way.—G. F. M.

Arsenic acids; Diazo synthesis of aromatic — and its theoretical significance in connexion with similar actions. A by-product containing arsenic. H. Schmidt. *Annalen*, 1920, 421, 159–174.

AROMATIC arsenic acids are prepared by the action of diazonium solutions on sodium arsenite (G.P. 250,261, 261,924; J., 1913, 1030). The most favourable conditions for the production of phenylarsinic acid and many of its nucleus substituted derivatives are secured when the alkalinity of the solution is so regulated that action can occur in accordance with the scheme: $\text{ArN}_2\text{Cl} + \text{AsO}_2\text{HK}_2 = \text{KCl} + \text{Ar.As}(\text{O},\text{HK}) + \text{N}_2$. In this manner, *o*-nitrodiazobenzene gives about 90% of the theoretical quantity of *o*-nitrophenylarsinic acid, but the amounts of arsenic-free by-products (azo-compounds etc.) are more considerable in the cases of many other arsenic acids. In more strongly alkaline solution the reducing action is more generally noticeable and the yields of arsenic acids are lower. Poorer yields are also observed with diazobenzene in acid solution, but an acid medium is favourable when strongly acidic substituents are present in the benzene nucleus. In addition to the well-known arsenic-free by-products, others containing arsenic can be isolated, the chief of which is phenylphenylenearsinic acid, $\text{C}_6\text{H}_5\cdot\text{C}_6\text{H}_4\cdot\text{AsO}_2\text{H}_2$. (*Cf.* J.C.S., Dec.)—H. W.

Civet. J. Nivière. *Bull. Soc. Chim.*, 1920, 27, 791–797.

A SAMPLE of civet was found to contain cholesterol and dextrose, and is thought to have been adul-

terated with wool fat and glucose syrup. Another sample was found to contain over 18% of talc powder.—W. G.

Antimony compounds; Aromatic —. I. Diazo-synthesis of aromatic stibinic acids and their polymeric constitution. *Aromatic derivatives of antimony pentachloride and its additive compounds*. H. Schmidt. *Annalen*, 1920, 421, 174–246.

THE action of diazo-compounds on antimony oxide is similar to that with arsenious acid (preceding abstract), nitrogen being copiously and spontaneously evolved and arylstibinic acids formed. The difficulty of retaining antimony oxide in solution with a little alkali can be surmounted by the use of potassium antimonyl tartrate and other soluble antimony salts or by the use of freshly precipitated hydrated antimony oxide which need not be completely dissolved. Reaction can frequently be effected in strongly alkaline solution, but when markedly acidic substituents are present in the benzene nucleus it is frequently preferable to operate in a neutral or acid medium. The arylstibinic acids are derivatives of polymeric antimonous acids (e.g., phenylstibinic acid $\text{O}(\text{H}.\text{SbC}_6\text{H}_5)_3(\text{O}.\text{O}.\text{SbC}_6\text{H}_5)_2(\text{O}.\text{O}.\text{H})$), which under the action of alkali and water yield the alkali salts of monomolecular arylstibinic acids, the latter, however, readily re-polymerising when liberated. They have pronouncedly colloidal properties. Antimony can frequently be estimated in arylstibinic oxides and triarylstibines which contain an amino group by direct titration with iodine in very dilute faintly acidic solution. If a group is not present which confers solubility in water, a suitable bicarbonate-alkaline solution can generally be obtained with the aid of tartaric acid and organic solvents. Alternatively about 1/1000 mol. of the substance is mixed with sodium chloride (0.2 g.) and sodium bisulphate (3 g.) in a Kjeldahl flask and boiled for 1 hr. with a mixture of nitric acid (sp. gr. 1.491, 1.5 c.c.) and concentrated sulphuric acid (10 c.c.). After cooling, ammonium sulphate (1 g.) is added and the solution is boiled for 30 mins. to expel nitric acid; it is subsequently diluted to about 300 c.c. and after addition of 5*N*-hydrochloric acid (20 c.c.) is reduced with sulphur dioxide and potassium bromide. The antimony is finally titrated with *N*/10 iodine in bicarbonate-alkaline solution (*Cf.* J.C.S., Dec.)—H. W.

Ichthyol oil and allied bituminous tar oils; Isolation of the active sulphur compounds of —. H. Scheibler. *Arch. Pharm.*, 1920, 258, 70–84. (*Cf.* J., 1920, 55a.)

THE typical sulphur compounds of ichthyol and other bituminous tar oils are derivatives of thiophene, which may be present in varying proportions up to as much as 50% in the case of ichthyol oil. From the purified oil (*loc. cit.*) by various reactions, particularly by treatment with less than the theoretical quantity of acetyl chloride and aluminium chloride, thiophene derivatives were isolated in a pure state.—G. F. M.

Cineol [eucalyptol]; Determination of — in essential oils. C. Kleber and W. von Rechenberg. *J. prakt. Chem.*, 1920, 101, 171–176.

THE solidifying point of the oil is determined in a jacketed vessel immersed in a mixture of ice and salt. Since the other constituents of eucalyptus oil are mainly hydrocarbons, the reference curves are obtained by observation of the solidifying temperatures of mixtures of cineol and rectified oil of turpentine; data are given over a range of 100% to 61% of cineol. In addition to hydrocarbons, the oil contains minor amounts of alcohols and aldehydes; the former, as exemplified by terpineol appears to raise the solidifying point, which is depressed by aldehydes as instanced by valeralde-

hyde. The results are accurate to within 1%. The process is not directly applicable to substances, such as cajuput oil, which contain less than 65% of cineol but may be utilised if a quantity of cineol equal to the weight of the oil is added.—H. W.

Acetone; Process for purifying —. J. Duclaux and A. Lanzenberg. *Bull. Soc. Chim.*, 1920, 27, 779–782.

ACETONE forms with carbon bisulphide a minimum boiling-point mixture. The acetone is mixed with 1.7 times its volume of carbon bisulphide and the mixture distilled, the product passing over between 35° and 40° C. being collected in three fractions. The acetone is extracted from these fractions by water and the aqueous extracts are distilled, the fraction boiling at 56.1°–56.3° C. being collected. If methyl alcohol is present in the acetone the minimum b.p. distillate of carbon bisulphide and acetone is left to stand over potassium carbonate before extraction with water, and copper sulphate is added to the subsequent aqueous extract before distillation. In this way most of the methyl alcohol is removed.—W. G.

Resin; Aldol condensation and formation of — by the action of dilute alkalis on acetaldehyde. H. Hammarsten. *Annalen*, 1920, 421, 293–315.

The action of the hydroxides of potassium, barium, and lead on dilute solutions of acetaldehyde at 0° C., 18° C., and 50° C. has been examined. The main reaction consists in the formation of aldols (the minimum quantity obtained being 40% of that theoretically possible), and this occurs even with very low hydroxyl-ion concentrations. Acetaldehyde, formed primarily, speedily passes into higher aldols which do not become converted into aldehyde resins as does the simpler substance. Aldehyde-resin consists of at least two substances, the red α - and β -acetaldehyde-resin described by Ekecrantz and a very pale yellow resin, m.p. 120°–130° C. after softening at 105° C. Acetaldehyde can be estimated in the presence of aldols by drawing purified air through the solution at 25°–30° C. and 25–30 mm. and then through a measured volume of N/5 iodine solution in the presence of N/1 potassium hydroxide; unused iodine is titrated with N/10 thiosulphate solution. Acetaldehyde (1 mol.) reacts with iodine (4 atoms) apparently in accordance with the scheme: $2\text{CH}_3\text{CHO} + 8\text{I} + 3\text{KOH} = 2\text{CHI}_3 + \text{H.CO.K} + \text{CH}_3\text{OH} + 2\text{KI} + 2\text{H}_2\text{O}$. Aldols are estimated, after removal of resin by filtration, by repeated extraction with ether, desiccation of the extracts with calcium chloride, removal of the solvent under diminished pressure, and weighing of the residue after exposure to phosphoric oxide at the ordinary pressure for 24 hrs. The aldols are subsequently volatilised at 120° C. and 10 mm., and any residual resin is weighed. (*Cf.* J.C.S., Dec.) —H. W.

Acetaldehyde; Determination of — in paraldehyde. W. Stüwe. *Apoth.-Zeit.*, 1920, 35, 153–154.

FIVE c.c. of the paraldehyde is added to a mixture of N/10 mercuric chloride solution 2 c.c., potassium iodide 2, 15% sodium hydroxide solution 20, and water 20 g., and, after 15 mins., the mixture is diluted to 100 c.c., and filtered; 50 c.c. of the filtrate is treated with gum arabic 0.5 g., sodium hydroxide solution 5, and formaldehyde solution 3 c.c., acidified, after 2 mins., with 15 c.c. of dilute acetic acid, cooled, and the separated mercury dissolved by the addition of 10 c.c. of N/10 iodine solution. The excess of iodine is then titrated with N/10 thiosulphate solution. Each c.c. of N/10 iodine solution = 0.0022 g. of acetaldehyde.—W. P. S.

Alcohols; Dehydrogenation of — by catalytic oxidation under reduced pressure. C. Moureu and G. Mignonac. *Comptes rend.*, 1920, 171, 652.

WHILST the method previously described (J., 1920, 247A) gives good results with alcohols of low mol. wt., it is found that with the higher alcohols it is preferable to pass the alcohol vapour and oxygen over the catalyst under a reduced pressure of 20–40 mm. and at 230°–300° C. Yields of 80–90% of the respective aldehydes may be obtained by this means from benzyl and cinnamic alcohols.—W. G.

Iodoform reaction [for detecting alcohol]; Sensitive modification of Lieben's —. R. Kunz. *Z. anal. Chem.*, 1920, 59, 302–303.

TEN c.c. of the dilute alcohol solution (e.g., 1 drop of alcohol in 100 c.c. of water) is treated with 2 c.c. of 10% sodium hydroxide solution, 0.15 g. of potassium iodide, and 0.2 g. of potassium persulphate, and heated at 50°–60° C. A turbidity, due to the formation of iodoform, develops in about 10 mins.—W. P. S.

PATENTS.

Chlorhydrins and bromhydrins of olefinic hydrocarbons; Manufacture of —. The Commercial Research Co., Assees. of B. T. Brooks. E.P. 128,578, 19.6.19. Conv., 20.6.18.

OLEFINIC hydrocarbons are converted into chlorhydrins or bromhydrins by subjecting them in the gaseous state, under a pressure of 5–6 atm., to the action of a weak aqueous solution of hypochlorous or hypobromous acid, respectively, of concentration preferably just under 0.15%. The aqueous medium is kept in continual circulation by means of a pump in a circuit comprising a pressure chamber in which the dilute acid solution sprayed in at the top meets and absorbs the olefinic gases forced in under pressure at the base, a storage tank into which the dilute chlorhydrin solution is discharged from the pressure chamber, and which communicates with a mixing vessel charged from time to time with sodium bicarbonate or other alkali salt of a weak acid, and finally a chlorinating or brominating chamber into which the alkaline solution from the mixing vessel overflows and reacts with halogen with the formation of sodium halide, carbon dioxide, and hypochlorous or hypobromous acid. Circulation is continued until a concentration of preferably 4.5%, but not exceeding 7%, of halogenhydrin is attained. The optimum temperature for an olefinic gas made by cracking petroleum products, and containing some 30–50% of ethylene and propylene, is about 15° C., and by regulating the pressure under which absorption takes place it is possible first almost quantitatively to convert the propylene from the gas into halogenhydrin without acting on the ethylene.—G. F. M.

Vanillylamine, vanillylacylamide, and production thereof. E. K. Nelson. U.S.P. 1,329,272, 27.1.20. Appl., 9.10.19.

VANILLYLAMINE, m.p. 131°–133° C., is prepared from vanillin by converting it into its oxime and reducing this with sodium amalgam and acetic acid. The corresponding acylamides, prepared from vanillylamine by the usual methods, are pungent substances which can be used in medicine in place of capsicum.

Di-(normal)-butylbarbituric acid. O. Kamm and E. H. Vollweiler, Assrs. to Abbott Laboratories. U.S.P. 1,331,712, 24.2.20. Appl., 23.1.19.

DI-N-BUTYLMALONIC ester, prepared by interaction of *n*-butyl bromide and malonic ester in presence of sodium ethoxide, is heated with sodium and alcohol and urea in an autoclave at 100°–110° C. After distilling off the alcohol from the reaction product, water is added, and di-*n*-butylbarbituric

acid precipitated by acidifying with hydrochloric acid. It forms white needles, m.p. 158° C., and has pronounced sedative properties together with low toxicity.

Ipecac alkaloids; Enteric preparation of —. J. K. Lilly, Assr. to The Eli Lilly and Co. U.S.P. 1,334,463, 23.3.20. Appl., 14.8.15.

CLAIM is made to a preparation containing the alkaloids of ipecacuanha combined with an adsorbent agent (Lloyd's reagent, hydrated aluminium and magnesium silicates; J., 1916, 651) capable of preventing the solution and absorption of alkaloids in the acid medium of the stomach, but releasing the alkaloids in the alkaline medium of the intestines.

Oils from the peel of citrus fruits; Process of extracting —. F. A. McDermott. U.S.P. 1,353,169, 21.9.20. Appl., 13.1.16.

THE peel is dried at a temperature below that at which the oil evaporates, and the oil is extracted from the residue, after grinding, by distillation under reduced pressure with a current of steam.
—L. A. C.

Acetone; Manufacture of — from acetic acid. Farbenfabriken vorm. F. Bayer und Co. G.P. 298,851, 8.3.16.

ACETONE may be produced by passing acetic acid vapour over a heated acetate or a base. If barium acetate is used, the reaction takes place at 320° C., or at a lower temperature under reduced pressure, and a quantitative yield results. Strontium carbonate, oxides of calcium and magnesium, or the corresponding acetates, may be substituted for barium acetate.—W. J. W.

Vapours [alcohol, ether] absorbed in sulphuric acid; Recovery of —. F. Herrmann. G.P. 300,733, 6.3.17.

THE solution in sulphuric acid, after dilution with water, is made to pass downwards through a series of chambers where it is submitted to direct or indirect heating by steam.—D. F. T.

Toxins; Production of Röntgen-, radium-, or thorium- —. E. Merck. G.P. 321,956, 30.9.17. Addn. to 257,473 (J., 1913, 507).

INTERNAL organs aseptically removed from animals are cooled by means of ice and subjected to Röntgen, radium, or thorium rays, and the decomposition products formed are dissolved in serum which has been similarly exposed to radiation. The serum is injected intravenously into living animals in increasing doses, and the animals are then treated according to the main patent. The tissues which have been exposed to radiation may alternatively be extracted with physiological salt solution containing radium emanation.—J. H. L.

Silver-protein preparations readily soluble in water; Production of stable —. Farbenfabr. vorm. F. Bayer und Co. G.P. 322,756, 12.5.16.

SILVER-protein compounds identical with or similar to those produced in accordance with G.P. 105,866, are mixed with urea or its derivatives (e.g., mono- or dimethylurea), with or without other suitable ingredients.—J. H. L.

Dihydroxyacetoxime; Preparation of —. C. H. Boehninger Sohn. G.P. 322,845, 1.12.17.

β -NITROPROPYLENEGLYCOL, or a salt thereof, is treated with reducing agents in presence of basic substances, such as hydroxides of alkalis or alkaline earths. Dihydroxyacetoxime may be almost quantitatively converted into glycerol.—W. J. W.

Yohimbine; Production of readily and perfectly soluble nucleic acid compounds of —. E. Weinert. G.P. 322,996, 26.7.17.

AMMONIA is added to a mixture of nucleic acid with yohimbé bases; or ammonium nucleate is allowed to interact with salts of yohimbine or of the total bases of yohimbé bark. Yohimbine nucleate, $C_{22}H_{33}O_5N_3 \cdot C_{10}H_{15}O_4N_3 \cdot P_1$, is a yellowish or greenish white amorphous powder with a slightly acid flavour and an almost neutral reaction. It is readily soluble in water, less soluble in alcohol, and insoluble in acetone or ether, and possesses therapeutic value.—J. H. L.

Arylurea; Preparation of an —. J. D. Riedel A.-G. G.P. 323,298, 20.12.17.

p-NITROPHENOL is treated with ethylenedichlorhydrin, and the amine formed by subsequent reduction is converted into the urea. *p*-Nitrophenol hydroxyethyl ether crystallises from aqueous solution as yellow needles, m.p. 94° – 95° C. The hydrochloride of *p*-aminophenol hydroxyethyl ether forms needles, m.p. 204° – 205° C., and its aqueous solution reacts with potassium cyanate to form the corresponding urea, m.p. 159° – 160° C.—W. J. W.

Glyoxal; Preparation of —. A. Wohl and K. Bräunig. G.P. 324,202, 30.6.16.

AIR or oxygen containing approximately 1% by vol. of ozone is passed through water and then mixed with $1\frac{1}{2}\%$ of acetylene in a large reaction space; a solution of glyoxal separates on the walls and bottom of the vessel.—D. F. T.

Hexamethylenetetramine; Preparation of derivatives of —. J. D. Riedel A.-G. G.P. 324,203, 11.6.14.

THE quaternary bases derived from hexamethylenetetramine, e.g., hexamethylenetetraminemethyl hydroxide and hexamethylenetetramine-ethyl hydroxide are combined with cholic acid; the resulting cholates are crystalline solids, soluble in water, and suited to the treatment of gall stones.—D. F. T.

Fatty acids and aldehydes; Method for the production of —. C. Harries, R. Koetschau, and E. Albrecht. G.P. 324,663, 29.2.16.

THE ozonides of unsaturated aliphatic oils derived from petroleum, or from the tar products of lignites, shales, peats, and asphalts, are decomposed, in solution if necessary, with formation of aldehydes or acids. A sample of gas oil from lignite tar yielded liquid acids, b.p. 80° – 220° C. under 10–12 mm. pressure, the fraction boiling at 180° – 200° C. at the same pressure containing solid fatty acids. The acids contained from seven to twelve atoms of carbon, and ranged from heptioic acid to lauric acid. The residual oil which resisted the action of ozone and of caustic alkali boiled at 260° – 330° C. and was of value for lubricating and for transformers.—D. F. T.

Glycerin substitute. G.P. 303,991. See XII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Colour photography and cinematography. W. V. D. Kelley. E.P. 129,638, 7.7.19. Conv., 8.7.18. See U.S.P. 1,337,775 of 1920; J., 1920, 468 A.

XXII.—EXPLOSIVES; MATCHES.

Detonation of explosives; Study of the causes governing the —. H. Kast. Z. ges. Schiess-u. Sprengstoffw., 1920, 15, 195–197.

THE phenomenon of detonation, induced by an initial impulse or shock, cannot be attributed to

the influence of air compressed in the interstices of the explosive. Experiments with pressed T.N.T. charges showed a diminution of the air content with rising density, and the velocity of detonation of T.N.T. filled into a tube was not appreciably different whether the explosion took place under normal atmospheric pressure or in an evacuated tube. If explosion were due to the effect of pressure in promoting the aggregation of the molecules, an increase of the explosion temperature with highly-compressed charges would be anticipated, but this is not the case. A probable interpretation of the problem is the disturbance of molecular stability, and this theory would account for the difficulty in effecting the detonation of dense charges having a rigid physical structure. Confirmatory evidence is found in the different initial impulses required for explosives of varying physical condition, though of similar chemical composition, and in the divergent velocities of detonation attained by them. The results obtained with explosives of various densities are tabulated. Nitrocellulose powders and gunpowder which, normally, achieve a velocity of ignition rather than of detonation, may nevertheless exert a disruptive effect if large quantities are involved.—W. J. W.

PATENTS.

Detonators; Blasting —. W. Eschbach. E.P. 151,572, 28.5.20.

ALUMINIUM is employed as the material for detonator shells, in which the detonating charge consists of lead azide, or lead azide mixtures, or tetryl with a top charge of lead azide, or other initiating composition which exerts no action on the aluminium. The advantages claimed for this metal, as compared with copper or brass, are the obviation of splitting when the shells are crimped on to the fuse, the freedom from oxidation, and the degree of hardness attainable which prevents distortion during pressing. The detonators are stated to have a greater coefficient of initiation, and to give a finer radiation, than those made with copper shells.—W. J. W.

Detonating agent; Initial —. W. O. Snelling. U.S.P. 1,353,805, 21.9.20. Appl., 6.5.20.

THE composition consists of lead azide prepared by the interaction of an alkali azide and a soluble lead salt in a solution of glue.—W. J. W.

Nitrating apparatus. Wülfling, Dahl und Co., A.-G. G.P. 300,079, 3.11.15.

THE interior cooler of a nitrating apparatus is provided with a flanged collar in which the pipe connexions are arranged, and which fits snugly between the flanges of the vessel and its lid when the apparatus is closed.—W. J. W.

Explosive; Gelatinised propellant — and process of preparing same. F. L. Nathan, W. Rintoul, and F. Baker (H. Baker, administrator), Assrs. to Nobel's Explosives Co. U.S.P. 1,338,691, 4.5.20. Appl., 26.2.14. Renewed 21.10.18.

SEE E.P. 4940—1 of 1913; J., 1914, 712.

Treating waste acids. G.P. 323,416. See VII.

XXIII.—ANALYSIS.

Thermocouples; Construction of — by electro-deposition. W. H. Wilson and T. D. Epps. Proc. Phys. Soc., 1920, 32, 326—340.

SMALL thermocouples suitable for the construction of batteries containing a large number of junctions may be constructed from a continuous coil of one of the metals which is coated, electrolytically, in suitable places with the other metal. If the elec-

trical conductivity of the latter element is considerably greater than that of the former, and a fairly thick sheath is deposited, a thermocouple is produced which is not appreciably impaired in efficiency by the short-circuiting effect of the core. Constantan wires coated with either copper or silver sheaths are suitable for most purposes.—J. F. S.

Gases; Apparatus for measuring the rate of flow of —. J. Erlich. Ann. Chim. Analyt., 1920, 2, 289—297.

THE pressure produced by the passage of the gas through a capillary connecting the two limbs of a U-shaped differential manometer is registered by the change in level of the liquid in the manometer, the apparatus being calibrated by actual measurement of the gas passed through the apparatus under definite conditions of pressure and time.—W. P. S.

Ultrafiltration; Use of — in toxicological analysis. C. Mannich and G. Wipperling. Ber. deuts. pharm. Ges., 1920, 30, 348—361.

ALTHOUGH substances such as oxalic acid, potassium chlorate, etc., may be separated by ultrafiltration (filtration through collodion membrane), this method cannot be recommended for general use. Small quantities of alkaloids and heavy metals, particularly mercury, are adsorbed by the membrane, and these quantities may be important where traces only of the substances are present. The adsorption of arsenic and antimony by the membrane is, however, practically negligible.

—W. P. S.

Refractometer; Analysis of aqueous solutions with the aid of the —. M. de Crinis. Z. physiol. Chem., 1920, 110, 254—266.

THE refractive index of salt solutions which do not manifest the phenomenon of molecular attraction is in direct linear proportion to the percentage concentration of the salt in the solution, and it is possible to calculate the percentage concentration by means of the formula

$$Y = (nD_x \% - 1.33320) / b,$$

where $nD_x \%$ = refractive index of $x \%$ solution, b = refractive index of 1% solution of the same salt, 1.33320 = refractive index of distilled water. The refractive index of a mixture of equal parts of various salt solutions is equal to the sum of the refractive indices of the separate solutions. If by mixing these salts some substance is precipitated the refractive index of the precipitated salt can be obtained by subtracting the refractive index of the remaining solution from the sum of the refractive indices of the component solutions. The ion content of the aqueous solution can therefore be calculated as follows:—

$$P = (nDR_x \% - nDO_x \%)/K,$$

where P = percentage, $nDR_x \%$ = refractive index of $x \%$ solution obtained by calculation, $nDO_x \%$ = refractive index observed after precipitation, $K = nDR_1 \% - nDO_1 \%$ of a 1% solution.—S. S. Z.

Volumetric analysis; Application of a new physico-chemical method of —. R. Dubrisay. Comptes rend., 1920, 171, 670—672.

THE method previously described (*cf.* J., 1918, 609 A; 1919, 103 A; 1920, 542 A) when applied to the neutralisation of sulphuric acid and sodium hydroxide, shows two points of inflexion on the curve, one corresponding to the formation of sodium hydrogen sulphate and the other to the formation of the normal sulphate. With mixtures of solutions of sodium sulphate and sulphuric acid the maximum difference between the observed and calculated temperatures is reached when the solutions are mixed in equimolecular proportions. The same is true for solutions of sodium sulphate and hydrochloric acid.—W. G.

Potassium; Determination of — as perchlorate, and its separation from sodium, etc. R. L. Morris. Analyst, 1920, 45, 349—368.

THE following procedure is recommended as the result of an exhaustive examination of the perchlorate method. After the potassium salt solution has been evaporated three times with 20% perchloric acid, the practically dry residue is stirred for 15 mins. with 10 c.c. of wash liquid (100 c.c. of 98% by vol. alcohol and 1 c.c. of 20% perchloric acid) and the liquid then decanted through a weighed Gooch crucible containing a layer of asbestos. If potassium only is present, the precipitate is rinsed directly on to the filter with a measured volume of the wash liquid. When sodium is present, the precipitate is heated to expel alcohol, dissolved in the minimum amount of boiling water, the solution evaporated to dryness, the treatment with 10 c.c. of wash liquid and the decantation repeated, and the precipitate rinsed on to the filter with 10 c.c. of the filtrate. The precipitate is washed on the filter with a measured volume of wash liquid, then dried at 130°—150° C. for 1 hr., cooled in a desiccator for 1 hr., and weighed; the weight is taken as being constant when, on washing with 3 c.c. of wash liquid, the difference between successive weighings does not exceed 0.2 mg. If the solution under examination contains phosphate, it should not be evaporated quite to dryness with perchloric acid, and the moist pasty residue should be treated with 15 c.c. of 98% alcohol previous to the treatment with the wash liquid. Calcium, iron, aluminium, and barium salts do not interfere. If magnesium is present, the evaporation must be stopped while the mass is still moist. Citric and tartaric acids tend to char during the evaporation with perchloric acid and a preliminary separation of the potassium as cobaltinitrite appears to be necessary. To determine potassium in potassium sulphate, the sulphuric acid is first precipitated with barium chloride, but it is unnecessary to remove the small excess of barium chloride used. At 15° C., 100 c.c. of the wash liquor dissolves 3.9 mg. of potassium perchlorate.—W. P. S.

Potassium; Determination of — as perchlorate. III. G. P. Baxter and F. E. Rupert. J. Amer. Chem. Soc., 1920, 42, 2046—2049. (Cf. J., 1920, 530 A.)

ETHYL alcohol denaturated with 5% methyl alcohol may safely be substituted for ethyl alcohol in washing potassium perchlorate. The temperature at which the washing takes place is unimportant if the washing liquor employed after the initial extraction is previously saturated with potassium perchlorate. (Cf. J.C.S., Dec.)—J. F. S.

Magnesium; Detection of —. F. Eisenlohr. Ber., 1920, 53, 1476—1477.

FIVE c.c. of a solution of alkannin in alcohol (96%) is treated with a drop of 2N-ammonium carbonate solution, which does not cause any change in colour, and then with a drop of the neutral salt solution to be tested; the presence of magnesium, strontium, or manganese is denoted by the development of a bluish-violet coloration, which becomes pale red after acidification with one or at most two drops of 2N-hydrochloric acid; subsequent addition of the same number of drops of 2N-ammonium carbonate solution restores the bluish-violet colour only if magnesium is present. If the test is to be applied to suspected magnesium ammonium phosphate, the salt is dissolved in 2N-hydrochloric acid and a drop of this solution is added to the alkannin solution; further addition of 1—2 drops of ammonium carbonate causes the appearance of the bluish-violet colour if magnesium is actually present, whilst

otherwise the original colour of the tincture is restored. It is essential that the alcoholic solution should not become diluted with water, since in this case a blue coloration is invariably produced which is due to ammonia formed by hydrolysis of the ammonium carbonate.—H. W.

Magnesium ammonium phosphate; Microchemical "two-phase reaction" for —. H. Kunz-Krause. Ber., 1920, 53, 1672—1673.

THE reaction is specially suited to the detection of magnesium ammonium phosphate in urinary sediments, but may be applied to the detection of phosphates generally. The solution of the sediment in acetic acid is neutralised with ammonia. On addition of a drop of silver nitrate solution, an egg-yellow, cheese-like deposit of silver phosphate is formed which disappears on addition of a drop of ammonia. At the same time the magnesium ammonium phosphate is deposited as colourless, shining prisms united in the form of rosettes. The reaction may be applied to the detection of phosphates as cellular enclosures in plant tissues.

—E. H. R.

Acidimetric determination of heavy metals in their salts. I. M. Kolthoff. Z. anorg. Chem., 1920, 112, 172—186.

EXPERIMENTS were made to determine with what degree of accuracy the salts of heavy metals which form insoluble hydroxides can be determined by titration with alkali hydroxides, either by the conductometric method or by the use of indicators. Magnesium sulphate gave satisfactory results by the conductometric method with barium hydroxide, and also by the indicator method using phenolphthalein. Zinc and copper sulphates gave unsatisfactory results by both methods. Mercuric chloride was determined satisfactorily by the conductometric method by titrating sodium hydroxide solution not greater than N/100 in strength with the mercury solution. In the case of aluminium salts, when these were titrated with sodium or barium hydroxide, a sharp break in the conductivity curve was not obtained at the neutral point, but there was a very sharp break at the point where the formation of aluminate was complete. Aluminium chloride or alum was successfully titrated with sodium hydroxide solution at the boil in presence of excess of barium nitrate, using phenolphthalein as indicator. Slight excess of alkali was run in and the excess titrated with acid. (Cf. J.C.S., Nov.)—E. H. R.

Iron; Separation of — from aluminium by precipitation as Prussian blue. H. Hale and G. O. Burr. J. Amer. Chem. Soc., 1920, 42, 2056—2058.

THE quantitative separation of iron from aluminium as Prussian blue cannot be effected, since the aluminium reacts with the excess of potassium ferrocyanide forming a jelly which cannot be handled. The precipitate of Prussian blue cannot be successfully filtered even after apparently perfect coagulation.—J. F. S.

Iron, mercury, and vanadium; Volumetric determination of — in the same solution. G. Hinard. Ann. Chim. Analyt., 1920, 2, 297—299.

To determine ferric, mercuric, and vanadic sulphates in sulphuric acid solution a portion of the latter is treated with hydrogen sulphide, the mercuric sulphide collected, oxidised with bromine, the solution then rendered alkaline with potassium hydroxide, and a measured excess of standardised potassium cyanide solution added; a few drops of potassium iodide solution are added as indi-

cator, and the excess of cyanide is titrated with silver nitrate solution. $\text{HgO} + 4\text{KCN} + \text{H}_2\text{O} = \text{K}_2\text{Hg}(\text{CN})_4 + 2\text{KOH}$. The filtrate from the mercuric sulphide is boiled to expel hydrogen sulphide, oxidised with bromine, and the iron precipitated as ferric hydroxide by treating the hot solution with potassium hydroxide; the ferric hydroxide is dissolved in hydrochloric acid, again precipitated (to remove remaining traces of vanadium), then dissolved in sulphuric acid and determined iodometrically. $\text{Fe}_2\text{O}_3 + 2\text{HI} = 2\text{FeO} + \text{H}_2\text{O} + \text{I}_2$. The iron and vanadium are then determined together iodometrically in another portion of the original solution; $\text{V}_2\text{O}_5 + 2\text{HI} = \text{V}_2\text{O}_4 + \text{H}_2\text{O} + \text{I}_2$. Slight modifications of the method are required when mercurous, ferrous, and vanadyl salts are also present.

—W. P. S.

Calcium group and magnesium; Precipitation of the —. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 1229—1234.

THE usual method of precipitating group IV. metals by means of ammonium carbonate is shown to be relatively insensitive, and the use of sodium carbonate in presence of sodium hydroxide is proposed. This throws down the metals of group IV. completely, together with magnesium, the former being separated from the precipitated carbonates by the chromate method, and reprecipitated by means of ammonium carbonate. (*Cf.* J.C.S., Nov.)

—S. I. L.

Nickel (cobalt); Electro-analytical separation of — from arsenic. N. H. Furman. J. Amer. Chem. Soc., 1920, 42, 1789—1793.

NICKEL may be quantitatively separated from salts of arsenic acid in ammoniacal solution by the electric current. Cobalt on deposition carries down arsenic, whereas the nickel deposit is free from arsenic. If the two metals are deposited simultaneously arsenic may or may not be deposited, according to the conditions.—J. R. P.

Zirconium; Determination of —. M. M. Smith and C. James. J. Amer. Chem. Soc., 1920, 42, 1764—1770.

ZIRCONIUM is precipitated by selenious acid from a boiling solution acidified with hydrochloric acid. The basic selenite on ignition leaves zirconia. This method gives satisfactory results in the determination of zirconium in a pure salt, in the separation of zirconium from aluminium and rare earths, and from iron when the amount of ferric oxide in the combined oxides of iron and zirconium does not exceed 10%. Titanium is precipitated together with zirconium, and a correction must be applied in this case or the precipitation carried out in the presence of excess of hydrogen peroxide, when zirconium alone is precipitated. If phosphates are present the zirconium phosphate in the ammonia precipitate is insoluble in hydrochloric acid, and must be fused with sodium carbonate, boiled with water, and the residue dissolved in hydrochloric acid and added to the main solution. For the determination of zirconium in zirconia ore, about 1.25 g. is fused with 12—15 g. of potassium hydrogen fluoride, the cooled melt is treated with 50 c.c. of sulphuric acid (1:1), heated gently at first and then more strongly until abundant fumes are evolved, cooled, boiled with water, and diluted to 250 c.c. 100 c.c. of the solution is diluted and precipitated with ammonia in presence of ammonium chloride. The precipitate is washed, dissolved by boiling with 36 c.c. of concentrated hydrochloric acid and 40 c.c. of water, diluted to 700 c.c., and precipitated with a 12.5% solution of selenious acid. The precipitate is collected, washed with 3% hydrochloric acid, dried, and ignited.—J. R. P.

Carbon monoxide; Determination of — in air contaminated with motor exhaust gas. M. C. Teague. J. Ind. Eng. Chem., 1920, 12, 964—968.

UNDER controlled conditions the apparatus devised by Graham (J., 1919, 10r) is capable of determining carbon monoxide in air with an accuracy of 0.005%, but in the case of air contaminated with motor exhaust gas, hydrocarbons must be removed before oxidising the carbon monoxide with iodine pentoxide. In a new portable apparatus described this is effected by passing the gas through U-tubes immersed in liquid air, which condenses the water, carbon dioxide, gasoline, and traces of other saturated and unsaturated hydrocarbons. The hydrogen, methane, and carbon dioxide pass into iodine pentoxide tubes, which are heated in an oil bath to 100°—175° C. Only the carbon monoxide is oxidised, the concentration of the hydrogen being too low to affect the results. The liberated iodine is absorbed by potassium iodide solution and titrated with sodium thiosulphate solution. A determination takes 15 mins., and should be accurate to 0.003—0.005% of carbon monoxide.

—C. A. M.

Hydrocarbons; Absorbent for heavy — [in gas analysis]. A. Piechota. Chem.-Zeit., 1920, 44, 797.

HEAVY hydrocarbons may be removed completely from a gas by passing the latter into an ordinary absorption pipette containing a saturated solution of potassium bichromate in concentrated sulphuric acid. About 10 mins.' contact is required, but it is better to pass the gas in and out of the pipette about twenty times.—W. P. S.

Fatty acids; Influence of electrolytic dissociation on the distillation in steam of the volatile —. J. Reilly and W. J. Hickinbottom. Sci. Prec. Roy. Dublin Soc., 1920, 16, 120—130.

THE deviations in the distillation constants of dilute solutions of volatile fatty acids (*cf.* J., 1919, 913 A) are explained on the basis of electrolytic dissociation. A mathematical expression to represent this and to correct the constants is given, and it is thus shown that the distillation constant is practically independent of the dilution. The effect of certain salts and acids in increasing the distillation constant of acetic acid is dependent on the nature of the salt added. (*Cf.* J.C.S., Dec.)—W. G.

PATENTS.

Hardness of ferrous metals; Testing —. L. W. Wild. E.P. 151,383, 30.6.19.

THE specimen is introduced within a standard magnetising coil, through which current is passed for a period somewhat less than a second. The speci-

men is removed and introduced into a ballistie coil connected with a fluxmeter, preferably of the Grassot type. The specimen is quickly withdrawn from the coil, and the resulting throw of the fluxmeter serves, after calibration of the instrument, to indicate the physical hardness of the specimen.

—J. S. G. T.

Thermo-elements; Protective covering for —.

Siemens und Halske A.-G. G.P. 322,919, 6.7.18.

As incombustible, insulating material, of a pulverulent nature, e.g., sand, fireclay, or magnesia, is packed into the protecting tube of the thermocouple.—W. J. W.

Colorimeter. F. G. Spindler, Assr. to A. Traeger.

U.S.P. 1,353,500, 21.9.20. Appl. 4.8.19.

The claims relate to means for supporting the materials to be tested in such a way that they can be moved away from or towards the eyepiece of the instrument.

Gas-colorimeter. W. G. Laird, Assr. to H. L. Doherty. U.S.P. 1,351,568, 5.10.20. Appl. 20.12.18.

A CURRENT of water is passed through a heat-absorption chamber in which the gas is burnt, and flows thence to a gas-reservoir, from which it displaces its own volume of gas, forcing it to the gas burner. Means are provided for measuring the temperature of the water passing through the heat-absorption chamber.

Removing carbon monoxide from gases. G.P. 303,931. See II A.

Soda-lime. U.S.P. 1,333,521. See VII.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

XXIII.—ANALYSIS.

APPLICATION.

Siemens u. Halske A.-G. Photometers. 30,637. Oct. 29. (Ger., 5.11.19.)

I.—GENERAL ; PLANT ; MACHINERY.

Catalysis; Promoter action in —, R. N. Pease and H. S. Taylor. *J. Phys. Chem.*, 1920, 24, 241–265.

PROMOTER action in catalysis is understood as including all those cases in which a mixture of two or more substances is capable of producing a greater catalytic effect than can be accounted for on the supposition that each acts independently and in proportion to the amount present. An example is furnished by the use of iron-molybdenum in the synthesis of ammonia. Iron and molybdenum are both catalysts for the reaction, but a mixture of equal parts of the two is much superior as a catalyst to either alone. A distinction is made between this type of activation (co-activation) and cases (activation) in which a relatively inert substance increases the activity of a catalyst. Neutral salt action is an example of the second type. Examples of promoter action in heterogeneous and homogeneous catalysis and enzyme action are given.

—J. R. P.

Vaporisation formula; Clausius' — and a comparison of the vapour pressure curves of two substances. F. A. Henglein. Z. Elektrochem., 1920, 26, 431—436.

A FORMULA has been derived which holds even to the highest temperatures, viz.,

in which T_1 and δ_1 are the boiling points of a substance at two different pressures, and T_2 and δ_2 the boiling points of another substance at the same two pressures. The constant, k , is approximately equal to the ratio of the molecular heats of vaporisation of the two substances at the same pressure. Another formula, $\log T_1 = a \log T_2 + b$, which holds up to the critical point, has also been developed. In this formula T_1 and T_2 are the temperatures at which both substances have the same vapour pressure, a and b are constants. It is possible by means of this formula to determine the vapour pressure curve of a substance from that of water.—J. F. S.

Gases from fire extinguishers. Fieldner and others.
See XIX_B.

PATENTS.

Dehydrating, reducing, calcining or roasting minerals and other pulverulent material; Apparatus for —. J. Réol. E.P. 130,978, 26.7.19. Conv., 9.8.18.

THE material is fed by a distributor at the top of a tower containing annular hearths arranged as steps in flights from the centre to the periphery and from the periphery to the centre. The material is pushed from step to step by rakes actuated by a central shaft and falls through a current of hot gas admitted at either end of the tower and exhausted at the other through a dust catcher.—B. M. V.

Extracting liquid from fresh peat, beet mass, and similar watery materials; Apparatus for —.
N. T. Thäberg. E.P. 151,907, 15.4.20.

A PRESS filter is formed of a number of flat elastic metal plates arranged edgewise side by side. The plates may be initially slightly curved or corrugated so that the spaces between them may be varied by moving the plates to or from one another. The plates are mounted on links to form an endless chain driven by sprocket wheels or rollers, and the chain passes between two converging plates to exercise pressure on the material and press the liquid through the filter. The converging plates may be

fixed or one may be an endless belt travelling in the same direction as the filter chain.—W. F. F.

Separating crystals from mother liquors containing more than one salt. J. T. Windram. E.P. 152,041, 13.8.18.

The mother liquor is centrifuged at an appropriate temperature and the crystal mass remaining in the centrifuge immediately treated with a fine spray of water or wet steam so that no substantial alteration of temperature of the mass occurs. The centrifuge continues to run during this treatment and during subsequent discharge of the crystal mass.

—J. S. G. T.

—J. S. G. T.

Distilling or recovering volatile inflammable liquid solvents; Process of —, W. K. Lewis and W. Green. E.P. 152,374, 31.1.19.

To remove benzol or gasoline from fabrics etc. the volatile solvent is evaporated by clean flue gas, being afterwards recovered by condensation or by washing with oil or other absorbent medium. The flue gas may be re-heated and used again.

—B. M. V.

Kilns; Continuous regenerative gas-fired — for burning ore briquettes and high temperature refractory materials. C. F. Priest. E.P. 152,509, 6.10.19.

TWENTY or more chambers are arranged on either side of a central main flue and each is provided with a controlled supply of gas. Through the dividing walls between adjacent chambers are passages providing communication either between adjacent chambers only or, in addition, by means of man-holes with the air or by means of a damper-controlled outlet with the main flue. The chambers are preferably worked in groups of seven, air being admitted (through the appropriate manholes) to the first chamber and gas to the middle chamber; in the first three chambers the material is cooled and the air heated, and in the last three chambers the material is pre-heated and the waste gases cooled. When the material in the fourth chamber is properly burnt the first chamber is cut out, and the eighth brought into operation.—B. M. V.

Mixer. J. Johnson. U.S.P. 1,354,489, 5.10.20.
Appl., 7.6.16. Renewed 21.2.19.

A ROTATING mixing wheel in a casing receives fluid to be mixed through central openings on opposite sides. The fluid is given a radial motion by centrifugal force and is directed to the side of the casing opposite to that of its entry.—W. F. F.

Grinding machine. J. Hereche. U.S.P. 1,355,093,
5.10.20. Appl., 25.1.17

A GRINDING roller is provided with longitudinal helical furrows separated by grinding ribs. A series of separate grinding bars are arranged parallel to the axis of the roller and at one side only, the faces of the grinding bars being corrugated or roughened to give a texture of increasing fineness from the upper to the lower bar. The bars are arranged with their upper longitudinal edges spaced further from the roller than the lower edges, so that a space of tapering cross-section is provided for the passage of the material.—W. P. F.

Tunnel dryer. Internat. Ges. für Trockenanlagen
m.b.H. G.P. (a) 322,783, 29.11.14, and (b)
322,784, 11.11.15.

(A) The goods are carried through the dryer on a series of wagons. The front wagon of the series acts as a connecting wagon and can be pushed into the blast-chamber, leaving the next one free to be taken away without difficulty. The connecting

wagon is then again connected with the train until another wagon is ready for removal. The connecting wagon is permanently attached by a flexible connexion to the mouth of the blast-chamber. (B) The dryer consists of a series of wagons divided into compartments and pushed against each other. Each wagon carries a part of the air-pipe and the last wagon, which is without divisions, is closed, so that it diverts the air back along the other wagons through a return pipe. By this means the air can be circulated backwards and forwards from the air-chamber over the material to be dried.—A. R. P.

Drying trough with fixed drum and revolving mixing and stirring shovels. W. Wurl. G.P. 323,462, 7.5.14.

The drying medium, e.g., hot air or gases, passes through a branched tube arranged along one side of the drying chamber, which is fitted with revolving discs carrying shovels, over the material to be dried, and out through a similar tube on the other side of the chamber. The revolution of the shovels through the slimy mass (e.g., sewage sludge), for the drying of which the furnace is especially designed, causes an intimate mixing of the hot gases with the material to be dried and also heats the stirring gear, so that the operation is carried out efficiently and quickly.—A. R. P.

Filtering membranes; Process for permanently glazing —. E. de Haën, Chem. Fabr. "List" G.m.b.H. G.P. 323,185, 29.8.17.

The moist discs of prepared filtering-membrane stretched on a frame are dipped for a short time in hot water or treated with steam, whereby a surface is produced which is so smooth that a completely air-tight connexion between the membrane and its support can be obtained. The membrane may be dried without any alteration of the physical properties of the surface.—A. R. P.

Washing and rectifying columns; Hood exits for —. H. Frischer. G.P. 323,295, 17.1.18.

The hood is provided with two, three, or more series of outlet openings so arranged that they are not in alignment in adjacent series. Between each series a partition is constructed with an opening at the foot so that an uninterrupted delivery of liquid and gas or vapour may be obtained.—A. R. P.

Distillation apparatus; Electrically heated —. Allgem. Elektrizitäts-Ges. G.P. 323,414, 26.10.18.

The liquid is heated by utilising its resistance according to the electrode principle in a special heater with which is combined a storage tank through which a condenser worm passes so that the condensation of the vapours from the heater serves to preheat a fresh quantity of liquid. By working in this manner it is possible to distil liquids by simply passing a current through them, and the heat economy obtained is much greater than in any previous apparatus.—A. R. P.

Perforated plate for apparatus for the mutual interaction of liquids and gases or vapours. H. Pauling. G.P. 323,296, 17.1.18.

The holes of the perforated plate are made conical from each side towards the middle, so that the plate may be used from either side. This has the advantage of requiring a smaller pressure for the same rate of flow of the same volume of gas through an equal number of holes; also the conical form ensures that during the passage of the liquid through the holes they become filled with liquid, which remains there by capillary attraction.—A. R. P.

Gases and vapours; Apparatus for treating — with liquids. H. Frischer and M. Drees. G.P. 323,474, 30.10.17.

The reaction chamber is subdivided by perpen-

dicular walls into separate compartments for the reacting liquids; each separate compartment is divided by horizontal walls into a series of superimposed chambers which are connected with one another in such a manner that the gases and vapours pass through the streams of liquid successively in each horizontal group in an up and down direction. While the gases are passing through the perpendicular chambers they come in contact with a number of different absorption liquids. It is possible in this apparatus to separate one and the same component from a number of different liquids without the residual liquids becoming mixed, and to rectify or purify gases and vapours.—A. R. P.

Ball or tube mills. N. L. Hall. E.P. 152,398, 8.7.19.

SEE U.S.P. 1,315,770 of 1919; J., 1919, 805 A.

Shaft-furnaces and such like; Blast-proof closing of discharging devices for —. H. Stebmann. E.P. 148,818, 10.7.20. Conv., 4.5.17.

Furnaces; [Burners for] oil-fired —. E. L. Woolley. E.P. 152,920, 2.3.20.

Catalysts. U.S.P. 1,329,322-3. See XII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Determination of the calorific value of the volatile matter of — as a measure of its suitability for gas manufacture. R. Mezger and M. Müller. J. Gasbeleucht., 1920, 63, 669-673.

The disadvantages of the methods of analysis described by Strache (J., 1911, 1245) and by Hiller (J. Gasbeleucht., 1916, 129) are pointed out, and the method of the authors is claimed to be simpler and more easily performed. The apparatus consists of a quartz tube of 12 cm. length and 6 mm. diam., which is sealed at one end. The other end is connected by capillary tubing with a Hempel gas burette. 0.2-0.5 g. of coal is weighed into the quartz tube, which is placed in a furnace heated by two Teclu burners, the temperature being maintained at 1000° C., using a Le Chatelier pyrometer for control. The tar is deposited on asbestos wool, filled into the free space in the quartz tube, this portion of the tube being cooled by water. The gas is cooled to atmospheric temperature, measured, and analysed, and from the analysis its calorific value can be calculated. With all coals studied, the calorific value of the volatile products was lower than that calculated by subtracting the calorific value of the coke from that of the original coal, whence it must be concluded that loss of heat took place due to exothermic reactions during gasification.—A. G.

Producer-gas and coal-dust firing; Comparative observations on the utilisation of heat in —. E. Terres. J. Gasbeleucht., 1920, 63, 673-675.

Tests were made with a lignite containing: moisture 53.63%, C 27.04%, H 1.72%, O 11.0%, N 0.39%, S 0.79%, and ash 5.43%. The calorific value of the raw lignite was 2500 Cals. per kg. For dust firing the lignite was dried to 15% moisture content and ground. The limiting temperature obtained by this method was 1850° to 2050° C., according to the amount of excess air added for combustion. In the second process "compound gas" was produced by carbonisation and subsequent gasification in lignite producers. The distillation gas produced from 100 kg. of lignite amounted to 20 cb.m. and contained 22.0% CO,,

1.0% heavy hydrocarbons, 11.0% CO , 48.0% H_2 , 10.0% CH_4 , and 5.0% N_2 , whilst the producer gas averaged 7% CO_2 , 25% CO , 10% H_2 , and 58% N_2 , and amounted to 119 cb.m. The temperature of combustion of the mixed gas is given as 1480° — 1625° C. By preheating the air supply to 850° C., this was increased to 1810° — 1960° C., whilst if the gas was also preheated to 850° C. before combustion, temperatures of 2080° C. (1 vol. of gas to 3 vols. of air) to 2250° C. (1 vol. of gas to 1 vol. of air) were attained. The author gives the thermal efficiencies of lignite-blast and gas-firing as 75.73 and 53.29 respectively, the difference representing the heat required to convert the lignite into gas.—A. G.

Flame; Propagation of — in mixtures of methane and air. *Part II. Vertical propagation. Part III. Propagation in currents of the mixtures.* W. Mason and R. V. Wheeler. *Chem. Soc. Trans.*, 1920, 117, 1227—1240.

WHEN mixtures of methane and air are ignited at the open end of a vertical tube closed at the other end, the first phase in the propagation of flame is the uniform movement. The speeds at which the flames travelled downwards with different mixtures were uniform over a considerable distance from the point of ignition, and were about two-thirds of those found for horizontal propagation in the same mixtures; transference of heat by convection presumably plays a considerable part in aiding the propagation of flame during the horizontal uniform movement. With upward propagation the flames sometimes began to vibrate within 50 or 60 cm. of the open end of the tube. The speeds over the whole range of mixtures were 3—5 cm. per second less when the flames travelled upwards than when they travelled horizontally. This slight difference probably arises from the difference in the shape of the flame front. Flames travelling upwards in mixtures containing 9—11% CH_4 were very sensitive to the effect of resonance of the tube, and could acquire either of two speeds, but not speeds intermediate between the two, the lower speed in the one case being shown, photographically, to be accompanied by, and probably due to, the setting up of resonance. The shape of the flame front was different when resonance was set up. If mixtures are ignited at one end of a vertical tube open at both ends, the tube acts as a chimney, and greatly enhanced speeds are obtained with flames travelling upwards owing to the effect of the draught and the turbulence it sets up in the mixture. Flame does not travel downwards if the mixture is ignited at the top of the tube, but continues to burn at the mouth of the tube. When the mixture is ignited at the closed end of a tube open at the other end the position of the tube does not affect the results. The lower limit of inflammability of methane, horizontal propagation, is 5.4% in a still mixture. With the mixture moving between 35 and 65 cm. per second along the tube, a flame passed through a mixture containing only 5.02% CH_4 , at the speed of the current. Comparatively gentle movement of the mixture along a tube resulted in greatly increased speed of flame, the major effect of the initial movement given to the mixture being evidently due to turbulence.—W. P.

Paraffin wax candles; Manufacture of —. Lach. Seifenfabr., 1920, 40, 325. *Chem.-Zeit.*, 1920, 44, Rep., 244.

THE wax is purified by treatment with heavy petroleum spirit, and with sulphuric acid (66° B., sp. gr. 1.84) at 120° C., and is decolorised by means of animal charcoal etc. Water is eliminated by melting the wax in jacketed vessels. For crystalline candles the melted wax is cooled to about 20° — 30° C. above its m.p., whilst for stearine-like candles it is stirred while it cools until it begins to solidify. Composite candles contain less than 5% of stearine.

Candles containing 2—3% of stearine and 5% of alcohol have a good appearance, but gutter when burned. The addition of a benzylnaphthol compound in place of alcohol improves the appearance, but not the burning qualities of the candles. Wicks with 24 threads are the most suitable for paraffin wax candles; wicks for night-lights must be coated with wax material.—C. A. M.

PATENTS.

Briquetting coal and other powdered material; Process for —. Rütgerswerke A.G., and H. Teichmann. G.P. 325,072, 18.4.19.

THE product obtained by heating coal with heavy coal-tar oils above 300° C., with subsequent removal of a portion of the oil, is employed as a binder in manufacturing briquettes.—L. A. C.

Gas retorts; Gas-producer furnaces for use in heating —. P. Litwin. E.P. 152,369, 21.1.18.

A GAS-PRODUCER furnace using coke is provided with a series of longitudinal water tanks below the stationary grate, each tank being covered by a section of the grate having small nozzle-like openings in the firebars. An injector nozzle is provided in the front of the furnace for each tank, so that a mixture of air and steam may be blown over the surface of the water below the grate-bars and then through the grate into the fuel. The furnace is suitable for using coarse coke and coko ash as it comes from the retort.—W. F. F.

Vertical retorts for carbonising coal. Woodall, Duckham, and Jones, Ltd., and W. T. Gardner. E.P. 152,548, 23.12.19.

TO secure a more uniform withdrawal of volatile products from vertical retorts of oblong cross-section, the mouthpiece is provided with transverse partitions in line with the sides of the hopper to confine the coal on its way from the hopper to the top of the retort. These partitions have openings in their upper parts to provide for the passage of gas from one side of the retort through the openings and above the coal in the mouthpiece to the outlet at the other side of the oblong section.

—W. F. F.

Gas producer. O. E. Yeo. E.P. 151,445, 21.8.19.

FUEL is supplied to the top of a producer which is conical at its upper end and cylindrical at its lower end. Air is blown in at the bottom and producer gas is drawn off through openings, arranged around the circumference about midway of the height, into an annular chamber surrounding the upper half of the producer and thence to the gas main. Another gas outlet is provided at the top of the conical part of the producer. A central refractory pipe, open at the top, projects upwards through the bottom of the producer to a level above the circumferential gas outlets, and steam may be supplied to the bottom of this pipe to generate water-gas. This water-gas may be drawn off from the top of the producer simultaneously with producer gas from the circumferential outlets. If the latter are closed the producer gas mixes with the water-gas. If the retort is charged with coal and the producer gas is burnt in the annular chamber, coal gas will be generated and mix with the water-gas. The producer may also be worked with downward draught.

—W. F. F.

Suction gas plants. F. D. Dilley. E.P. 152,380, 15.5.19.

FUEL is admitted into the top of a vertical producer,

and air for primary combustion is admitted horizontally at the side near the top. A gas outlet for heavy hydrocarbons is arranged immediately opposite to the air inlet, and the gas is led downwards through an external pipe to the bottom of the producer. Steam and air are also admitted at the bottom of the producer in controlled amounts for secondary combustion, and a ring of gas outlets is provided about midway of the height of the producer. The gas is led through a jacketed pipe to a washer, and steam or hot water from the jacket is led to the base of the producer. The apparatus is suitable for use with bituminous material, coconut shells, rubber seed husks, and sawdust.—W. F. F.

Mineral oils which have been treated with [sulphuric] acid; Neutralising —. G. Grisard. E.P. 136,169, 4.12.19. Conv., 4.12.18.

The oil is agitated at 50°–70° C. with anhydrous sodium or potassium carbonate and calcium chloride.—L. A. C.

Lubricant from naphthene acids; Manufacture of a —. C. Francke. G.P. 324,227, 5.10.17.

NAPHTHENE acids are purified by means of a mixture of fullers' earth and sulphur dioxide, and then separated by filtration. The filtrate is heated to 200° C., and again heated after addition of nickel formate, and subjected to the action of hydrogen until the temperature reaches 300° C.—W. J. W.

Peat; Manufacture of fuel from —. N. de Long. E.P. 152,515, 11.10.19.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Gas; Disappearance of — in the electric discharge. Research Staff of the General Electric Co., Ltd., London (N. R. Campbell and J. W. H. Ryde). Phil. Mag., 1920, 40, 585–611.

THE disappearance of gas in vessels under the influence of an electric discharge is closely connected with the appearance of a glow in the vessel. This glow appears sharply at a definite potential difference between the electrodes. The glow potential is of great importance for interpreting the rate of disappearance of the gas. The experimental results are explained by supposing that the glow causes a reversible chemical change to occur in the gas. (Cf. J.C.S., Dec.)—J. F. S.

Photometer. Eder. See XXI.

PATENTS.

Retorts [for distillation of solid materials]. J. E. Kennedy. E.P. 141,028, 20.2.20. Conv., 31.3.19.

A HORIZONTAL rotating retort tapers from the outlet towards the inlet end and carries trunnion members at each end which rotate against stationary feed and discharge conduits of the same diameter. The retort is built up of a number of sections having in-turned flanges which are screwed together, and internal longitudinal ribs are provided to transmit the heat to the material. Raw material is fed into

the smaller end of the retort from a hopper by means of a reciprocating plunger, and the solid residue is removed at the other end by a number of radial blades which lift it on to a guide cone, having its apex pointing towards the discharge trunnion. The residue passes into the fixed discharge conduit and thence to a water seal. A perforated pipe projects longitudinally into the inlet end of the retort to withdraw gaseous products, and steam may be admitted at the discharge end of the retort.

III.—TAR AND TAR PRODUCTS.

Nitro-derivatives of toluene; Synthesis of some —. O. L. Brady and P. N. Williams. Chem. Soc. Trans., 1920, 117, 1137–1140.

3,4-DINITROTOLUENE was prepared from o-toluidine by nitrating to 4-nitro-o-toluidine by Noelling's method (Ber., 1884, 17, 265), acetylating, and further nitrating with fuming nitric acid and sulphuric acid to a mixture of 3,4- and 4,5-dinitro-aceto-o-toluidines, which gave the corresponding dinitrotoluidines on hydrolysis. Up to this stage the yields were good, but on removing the amino-group with nitrous acid only 2 g. of pure 3,4-dinitrotoluene was obtained from 9 g. of the mixed dinitrotoluidines. Although separation of the two isomerides is not necessary for the preparation of 3,4-dinitrotoluene, they are readily isolated by fractional precipitation with water from the solution in 50% sulphuric acid resulting from the hydrolysis of the acetyl derivatives, and if individually treated with Caro's acid, and finally nitrated with fuming nitric acid give good yields of 2,4,5- and 2,3,4-trinitrotoluenes respectively.—G. F. M.

Nitro compounds; Analysis of aromatic — by means of titanium trichloride. F. L. English. *J. Ind. Eng. Chem.*, 1920, 12, 994—997.

MONONITRO-HYDROCARBONS are very resistant towards reduction by titanium trichloride, but the presence of positive or negative substituents, with the exception of chlorine, in the nucleus facilitates the reduction of the nitro groups. The position of the substituents with regard to the nitro group has no appreciable effect; *m*- and *p*-nitroaniline are reduced with equal ease, as are *o*- and *p*-nitrophenols, *o*- and *m*-nitro-*p*-toluidines, and 5-nitro- and 3-nitro-salicylic acid, whilst *o*- and *p*-nitrochlorobenzenes are about equally refractory. (Cf., Callan, Henderson, and Strafford, *J.*, 1920, 86 r.)—W. P. S.

Nitrohydrocarbons; Action of aluminium chloride on solutions of — in aromatic hydrocarbons. A. Kliegl and H. Huber. *Ber.*, 1920, 53, 1646—1655.

THE action of anhydrous aluminium chloride on a boiling mixture of toluene and nitrobenzene leads to the formation of much resinous matter and small amounts of *p*-aminophenyl-*p*-tolyl, m.p. 99° C., b.p. 190° C. at 18 mm., and phenyl-*p*-toluidine, m.p. 88°—89° C. (Cf. *J.C.S.*, Dec.)—H. W.

PATENTS.

Benzol or the like; Purification of —. South Metropolitan Gas Co., E. V. Evans, and H. Hollings. E.P. 152,470, 16.8.19.

THTOPHENS are removed from benzol by treating the benzol with 60—85% sulphuric acid at 30°—90° C., or by passing benzol vapour through 73—82% sulphuric acid.—L. A. C.

Hydrocarbons; Continuous purification and neutralisation of liquid —. H. Heinemann and A. Hellmann. G.P. 325,230, 27.9.17.

THE hydrocarbon, e.g., benzol, is passed continuously through vessels containing successively sulphuric acid and sodium hydroxide solution, and the purified hydrocarbon is withdrawn through jackets surrounding the vessels in order to allow of regulation of the heat of reaction.—L. A. C.

Acid sludge produced in the purification of benzol; Process and apparatus for dealing with the —, and for recovering benzol and its homologues therefrom. G. Stephenson. E.P. 152,054, 2.5.19.

THE acid sludge is heated in a wide, shallow pan by steam introduced through a perforated lead pipe at the bottom of the pan. The benzene vapour as it passes into an outlet pipe at the top of the vessel is scrubbed by a spray of ammonia gas or of a solution of ammonium carbonate, whereby benzenesulphonic acid is converted into benzene and ammonium sulphate. The vapour then passes through a scrubber containing dilute sulphuric acid to remove any excess of ammonia, and thence to a condenser.—L. A. C.

Thionaphthene; Process of separating — from coal-tar [naphthalene]. Ges. für Teerverwertung m.b.H. G.P. 325,712, 8.7.19.

THE sulphonic acid produced as by-product in the technical purification of naphthalene, i.e., by treatment of the crude naphthalene with sufficient sulphuric acid to sulphonate only a fraction of the material, is hydrolysed by steam distillation at 145° C. The product contains about 12% of thionaphthene, and by further partial sulphonation and subsequent hydrolysis an oily product, containing about 36% of thionaphthene, is obtained, which on treatment with the calculated amount of mercury acetate in boiling methyl alcohol yields a crystalline double compound of thionaphthene and mercury acetate. The crystalline product is separated from

the solution, washed, and decomposed to yield pure thionaphthene. (Cf. *J.*, 1920, 716 a.)—L. A. C.

IV.—COLOURING MATTERS AND DYES.

Azopyrazolones; Some new — and allied compounds. K. H. Saunders. *Chem. Soc. Trans.*, 1920, 117, 1261—1272.

A COMPLETE series of compounds has been prepared in which the anthraquinone nucleus is introduced either into the 1-position of the pyrazolone ring, or as the first component of an azo-pyrazolone compound, or in both positions together. 1-β-Anthraquinonyl-3-methyl-5-pyrazolone was obtained by condensing ethyl acetoacetate with β-anthraquinonylhydrazine, dehydrating the resulting hydrazone by boiling with acetic anhydride, and finally removing the acetyl group by hydrolysis with hydrochloric acid. It is a highly insoluble orange powder which couples with diazonium salts to give stable arylazopyrazolones, the benzene-azo-compound being yellow, and the α- and β-naphthalene-azo-compounds vermilion and red respectively. 4-β-Anthraquinone-azo-anthraquinonylmethylpyrazolone forms yellow needles from nitrobenzene; it is practically insoluble in all other solvents. All the anthraquinone-azo-pyrazolones, whether unsubstituted in the 1-position or substituted by phenyl, naphthyl, or anthraquinonyl residues as in the above-mentioned compound, are similarly sparingly soluble. They dissolve, however, in warm alkali hydroxide to deep purple solutions. The 1-phenyl- and 1-β-naphthyl-compounds can exist in a yellow unstable, and a red stable modification, both of which give the same absorption spectrum. On the other hand the 1-anthraquinonyl- and the 1-unsubstituted compounds exist only in the yellow forms.—G. F. M.

Catechin; Constitution of —. II. M. Nierenstein. *Chem. Soc. Trans.*, 1920, 117, 1151—1156. (Cf. *J.*, 1920, 685 a.)

3,4,2',4',6'-PENTAMETHOXY-α-α-DIPHENYLPROPANE, which was previously found to be identical with the methylated reduction product of Kostanecki and Lampe (*loc. cit.*), has been synthesised from 3,4,2',4',6'-pentamethoxydiphenylacetyl chloride by converting this, by treatment with diazomethane, into the corresponding pentamethoxydiphenylmethyl chloromethyl ketone, and reducing this latter substance with sodium and alcohol.—G. F. M.

Pyrrole Blacks. VIII. A. Angeli and C. Lutri. *Atti R. Accad. Lincei*, 1920, 29, i., 420—423.

THE black substance formed from pyrrole and quinone is obtained also when these compounds react in acetic acid solution and hence probably represents an individual compound and not a mixture (cf. *J.*, 1920, 329 a). Pyrrole and *p*-nitrosophenol react in cold acetic acid solution giving an amorphous, deep violet-black powder of the formula C₂₂H₁₂O₃N₂ or C₂₂H₁₂O₃N₂ (cf. Angeli and Cusmano, *J.*, 1917, 923). Intensely coloured products are formed also by the action of pyrrole on *p*-quinone-imino and *p*-quinonedimine.—T. H. P.

Carbocyanines. Mills and Pope. See XX1.

PATENTS.

Azo dyestuffs; Manufacture of —. P. A. Newton. From Farbenfabr. vorm. F. Bayer und Co. E.P. 3557, 11.2.14.

YELLOW azo dyestuffs, which can be rendered very

fast to washing by after-treatment on the fibre with formaldehyde, are obtained by coupling with aminopyrazolones the tetrazo compounds prepared from the aminobenzoylamino compounds described in F.P. 426,201 and E.P. 18,205 of 1911 (J., 1911, 948; 1912, 678), and the monodiazoo compounds of the sulphonic acids of aminobenzoylaminothiozole compounds (G.P. 163,040; J., 1906, 216). The dyes can be developed on fibre and yield pure whites when discharged with hydrosulphite.

Disazo dyestuffs able to be chromated. E. Reber, Assrs. to Soc. of Chem. Ind. in Basle. U.S.P. 1,338,397, 27.4.20. Appl., 24.8.18.

Disazo dyestuffs are prepared from aromatic diazoazo compounds and hydroxycarboxyarylpiazolones. They are orange to brown powders dissolving in water to form orange to brownish-red solutions and in concentrated sulphuric acid to red to blue solutions. They dye wool in an acid bath clear red to orange and brownish-red tints, which when chromed become fast to fulling and to potting.

Disazo dyestuffs dyeing mordanted fibres. C. Jagerspacher and M. Isler. Assrs. to Soc. of Chem. Ind. in Basle. U.S.P. 1,338,506, 27.4.20. Appl., 17.8.18.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Hardwoods; Proximate analysis of —. Analysis of *Quercus agrifolia*. W. H. Dore. J. Ind. Eng. Chem., 1920, 12, 984—987.

SLIGHT modifications of methods used previously for coniferous woods (J., 1920, 400 A, 513 A) were applied to the analysis of hardwoods. The purification treatment employed for coniferous woods (successive extraction with benzene and alcohol) was supplemented by digestion with cold water and with cold 5% sodium hydroxide solution; these treatments removed all adventitious matter without injuring the cellulose or lignin. The latter was determined by König and Becker's hydrogen chloride method (J., 1919, 530 A). Oak (*Q. agrifolia*) wood yielded the following results:—Loss on drying, 4.20; benzene extract, 0.50; alcohol extract, 4.33; soluble in cold water, 3.66; soluble in cold 5% NaOH solution, 18.71; cellulose, 45.48; lignin, 20.25; pentosans not otherwise accounted for, 1.89; mannan (residual), none; galactan (residual), 1.49; total, 100.51%.—W. P. S.

Lignin and reactions of lignin. P. Klason. Ber., 1920, 53, 1862—1863. (Cf. J., 1919, 570 A; 1920, 482 A.)

YELLOW cyclic naphthylamine salts, similar to those obtained from pine, have been prepared from fir, beech, birch, oak, linden, alder, and aspen. The corresponding salts obtained from herbaceous plants have a different composition.—H. W.

Pine lignin; Constitution of —. P. Klason. Ber., 1920, 53, 1864—1873. (Cf. *supra*.)

THE lignin which contains an acrolein group and, in the form of its sulphonic acid, yields cyclic arylammonium salts and a calcium salt precipitable by calcium chloride, is termed acrolein-lignin or α -lignin, whilst the second variety, which does not exhibit this behaviour but which contains a free carboxy group, is named carboxylignin, or β -lignin. The two varieties can be quantitatively separated by β -naphthylamine hydrochloride; a complete proximate analysis of pine wood can therefore now be effected giving carbohydrates (68%), lignin (30%), and other substances (2%), 63% of the lignin being present as the α variety and 37% as the β form.

The formulæ, $C_{22}H_{22}O_8$, and $C_{13}H_{10}O_8$, are advanced for α -lignin and β -lignin respectively, and reasons are given for considering the former to be a derivative of flavone. (Cf. J.C.S., Dec.)—H. W.

Straw lignin. F. Paschke. Wochenbl. Papierfabr., 1920, 51, 1139—1141, 2322—2323. Chem. Zentr., 1920, 91, IV., 53, 485.

TREATMENT of straw with sodium carbonate produces good yields of straw pulp if attention is paid to control of temperature and concentration. About 50% is obtainable from rye straw. From the alkaline extract a granular, reddish-brown powder, which decomposes at 195° C., and has the formula $C_{22}H_{21}O_8$, was isolated. It has a higher content of oxygen than wood-lignin. It forms a colloidal solution with water and is precipitated by solutions of barium chloride, calcium chloride, and other metallic salts. Waste liquors from the treatment of straw with sodium carbonate contain no combined ammonia, as is the case when sodium hydroxide is used, which indicates that the protein of the straw is not decomposed.—W. J. W.

PATENTS.

Vegetable fibres; Process for obtaining — for textile purposes. Deutsche Faserstoff-Ges. Fulda m.b.H. G.P. 324,333, 11.1.19.

FIBROUS parts of plants are heated with an alkaline solution of sodium silicate to which an electrolyte is added. The gelatinous silicic acid formed effects separation of the fibres from incrustants.—W. J. W.

Nettle fibres; Treatment of — for textile purposes. Nessel-Anbau-Ges.m.b.H. G.P. 324,519, 10.9.18.

NETTLE fibres may be made crisp and stronger by treatment with strong alkali liquors or other alkaline solutions.—W. J. W.

Fibres; Production of — from plants. Nessel-Anbau-Ges.m.b.H. G.P. 324,520, 15.9.18.

PLANTS such as nettle, sedge, broom, ramie, reha, etc., are treated with a neutral alkali aluminate, which has no deleterious action on the fibres.—W. J. W.

Plants; Process for separating fibres from —. Nessel-Anbau-Ges.m.b.H., and A. Hoermann. G.P. (A) 325,887, 10.4.18 and (B) 325,888, 15.9.18.

(A) ALBUMINOUS and starchy constituents are removed from the fibres by the action of diastatic enzymes before the material is boiled. (B) The appearance and pliability of the fibre are improved by the addition of glycerin or a lactic acid ester to the water or alkaline solution in which the material is boiled.—L. A. C.

Artificial silk solutions; Process for precipitation and purification of —. A. Thilmany. G.P. 324,334, 14.9.19.

ACIDIFIED water or a weak salt solution is sprayed into a bath of the usual precipitating solutions through nozzles, which are fixed between two electrodes. The precipitated, or superficially coagulated fibres are thus hardened and purified.—W. J. W.

Viscose; Bath for spinning threads from —. J. C. Hartogs. G.P. 324,433, 1.3.14.

THE bath consists of a dilute solution of sulphuric acid containing not less than 7% H_2SO_4 , to which two or more soluble sulphates are added in such quantities that not less than 5 equivs. of SO_4 ions are present for every 3 equivs. of H ions. A suitable solution for viscose which has been kept for 7—8

days consists of Na_2SO_4 , 16 parts; $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 30 parts; H_2SO_4 , 9 parts; and water, 45 parts.

—W. J. W.

Hemicellulose; Manufacture of — from wood by the soda process. T. and E. Kuttelsen. G.P. 324,053, 4.3.19. Conv., 20.1.19.

Wood is reduced to small fragments and boiled with clarified "black liquor," after which it is boiled under pressure with a mixture of fresh liquor and "black liquor." It is then washed, ground, and subjected to further treatment.—W. J. W.

Cellulose; Process of obtaining — in two stages. C. S. Fuchs. G.P. 324,894, 2.5.18.

VEGETABLE matter, especially straw, is boiled with alkaline lyes, at the ordinary or increased pressure, until a solution rich in lignic acid is obtained, and the boiling process is then completed with fresh lye. The lignic acid precipitated from the first solution can be used as a resin substitute etc.—C. A. M.

Cellulose esters; Preparation of lacquers, and solutions or masses of —. Chem. Fabr. von Heyden A.-G. G.P. 324,786, 29.8.17.

ESTERS of acyl-hydroxy-fatty acids are used in the preparation of lacquers etc. The ethyl ester of acetylhydroxyacetic acid yields flexible films with cellulose acetate, and nitrocellulose forms very elastic sheets on treatment with the amyl ester of acetylglucolic acid.—C. A. M.

Cellulose waste lyes; Decolorisation of —. A. Wipfler. G.P. 324,787, 1.4.19.

CELLULOSE waste lyes are treated with metals or their compounds (stannous chloride, metallic chromium and hydrochloric acid, chromic acid with aluminium bisulphate) capable of forming insoluble colour-lakes with the colouring matter.

—C. A. M.

Paper; Manufacture of dense strong —. C. G. Schwalbe. G.P. 323,745, 21.2.18. Addn. to 303,498.

PAPER stock, or cellulose waste, is treated with acid, after which it is subjected to mechanical treatment in edge runner mills or disintegrators, and the gummy material so obtained is added to paper pulp.

—W. J. W.

Paper; Manufacture of waterproof —. H. Wandrowsky. G.P. 323,816, 13.6.19.

CELLULOSE esters, insoluble in water, are added to paper pulp, and the paper, after drying, is treated with a soluble solvent for gelatinising the cellulose esters. In the case of paper textiles the solvent is not added till after the weaving process.—W. J. W.

Sizing paper; Material for — obtained from the waste liquors in the Mitscherlich cellulose process. A. Michl. G.P. 323,865, 16.1.19.

WASTE liquors from the Mitscherlich process are exposed to air for a short time, and then centrifuged, a concentrated emulsion of the resinous constituents of any required density being thus obtained. The sizing material is fixed by means of alum.—W. J. W.

Drying paper or other material in sheet form; Method of and apparatus for —. O. Minton. E.P. 152,928, 26.3.20.

Acetates. U.S.P. 1,339,040. See VII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Washing or scouring wool; Process and apparatus for —. R. M. Poole and H. F. Davis. E.P. 152,513, 10.10.19.

Wool is scoured with a solution containing, e.g., 2–5 oz. of potassium carbonate, 2–5 oz. of sodium sulphate, 0.1 oz. of potassium chloride, and 0.25 oz. of sodium chloride per gall., and is subsequently washed with water. The solution, after it has been used for scouring, is concentrated, and the residue is dried and calcined. The product is dissolved in water, and the solution, after filtration and addition of fresh potassium carbonate, is employed for scouring more wool. Any fat rising to the surface during scouring or evaporation of the solution is recovered.—L. A. C.

Fulling process. C. H. Boehringer Sohn Chem. Fabr. G.P. 324,575, 10.5.19.

SALTS of bile acids (e.g., cholic and taurocholic acids) are used for fulling, whereby the amount of soap required is reduced, and the fibres are protected from the action of alkalis. Suitable solutions contain sodium carbonate, 3%, and sodium cholate, 0.1%, or ammonium carbonate, 2%, and potassium taurocholate, 0.2%.—W. J. W.

Stk; Method of loading —. Deutsche Gasglühlicht A.-G. (Auerger.). G.P. 324,562, 30.10.17. Addn. to 320,783 (see E.P. 116,102; J., 1920, 17a).

TREATMENT of the fibres with alkaline gases is followed immediately by treatment with phosphates or silicates, after removing excess of alkali by suction or ventilation.—W. J. W.

Broom corn; Treating [dyeing] —. H. J. Broderson and S. W. Parr. U.S.P. 1,337,306, 20.4.20. Appl., 19.7.16.

BROOM corn is treated with a hot aqueous solution containing a substance, such as sodium sulphite or bisulphite, which facilitates the solution of the objectionable red colouring matter. A reagent, such as aluminium or chromium sulphate or a copper, nickel, tin, or uranium salt, is then added to form an insoluble precipitate with the dissolved colouring matter, and a protective colloid, e.g., glue or casein, is also added to prevent too rapid hydrolysis of the precipitating salt. After removing the fibre from the solution and precipitate, it is dried and then dyed.

Textile fabrics; Sizing of —. A. Poulson. E.P. 152,096, 4.7.19.

CHINA clay (3–4 pts. by measure) is added to a solution of 3 pts. of neutral sodium silicate in 3–4 pts. of water, the mixture is agitated, and, after settling, is sifted to remove lumps. The composition may be used direct, or may be dried and ground, and subsequently made into a paste with water as required.—L. A. C.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric and nitric acids; Distillation of mixtures of —. J. Baumann. Chem.-Zeit., 1920, 44, 805.

A MIXTURE of nitric acid and sulphuric acid (sp. gr. 1.84) cannot be completely separated into its components by distillation. Recovery of the nitric acid without loss of sulphuric acid can only be effected by dilution and re-distillation of the mixed acid residue from the first distillation, which is not a

practicable operation. In two experimental distillations of diluted mixed acid prepared from sulphuric acid of sp. gr. 1·84 and nitric acid of sp. gr. 1·40 (64·5% HNO_3) and 1·30 (48% HNO_3), respectively, in the first case 94·8% of the nitric acid was recovered as acid of 92% strength and 5% was retained by the waste sulphuric acid, whilst in the second 88·6% of the nitric acid was recovered as concentrated acid, and 11·3% was left in the residue. Decrease in concentration of the nitric acid therefore necessitates the use of a disproportionately larger amount of sulphuric acid as water-absorbing medium, and also results in an appreciably larger percentage of nitric acid retained by the sulphuric acid. Dilute nitric acid, such as that derived from the ammonia oxidation process, e.g., of 34°–40° B. (sp. gr. 1·30–1·38) should be concentrated to at least 42° B. (sp. gr. 1·44) in a dephlegmating column, and the waste sulphuric acid should be denitrated. Some loss of nitric acid may arise from the action of reducing substances, such as arsenic, selenium, and organic matter, in the sulphuric acid.—W. J. W.

Distillation of a ternary mixture [e.g., sulphuric acid, nitric acid, and water], one constituent of which is not volatile. P. Pascal. Bull. Soc. Chim., 1920, 27, 814–820.

A MATHEMATICAL discussion of work already published (J., 1917, 1232). The results are applied to the concentration, by distillation with sulphuric acid, of nitric acids of different strength.—W. G.

Atmospheric nitrogen; Fixation of — as cyanide. T. Thorssell. Z. angew. Chem., 1920, 33, 239–240, 245–247, 251–254.

In the fixation of nitrogen as cyanide by its interaction with a mixture of carbon and carbonate of barium or sodium, intimate admixture of the materials is essential, and the addition of manganese, nickel, or iron has been recommended; the use of the last-named metal, in the case of sodium carbonate, admits of a working temperature of 930° instead of 1000°–1100° C., and thus reduces loss of cyanide. The effect of impurities in the carbon, such as silica, alumina, magnesia, or lime, is deleterious and cumulative. Increase of temperature and of pressure correspondingly accelerate the reaction. A preponderance of cyanide over carbonate has a retarding action, but this is not realised in a continuous process, as the partial pressure of the nitrogen is greatest at that part where most cyanide is present. The most important condition governing the process is the relative proportion of nitrogen and carbon monoxide, and in order to avoid accumulation of the latter it must be removed by a stream of nitrogen. A cheap

monoxide formed in the cyanide process or by water-gas, but as the limits within which reduction takes place, without separation of free carbon or formation of carbon dioxide which would contaminate the nitrogen, are restricted, a proportion of carbon dioxide must be added (to prevent separation of free carbon which would subsequently be oxidised to carbon dioxide) when water-gas is employed as reducing agent. The reactions which take place in the furnace and the energy consumption are compared in the two cases where barium carbonate and sodium carbonate respectively are used. As regards advantages offered by these two carbonates, the former is less liable to cause overheating, and gives a very stable basic cyanide, $\text{BaO} \cdot \text{Ba}(\text{CN})_2$. On the other hand, the sodium cyanide formed by use of sodium carbonate is more serviceable as the starting-point for the manufacture of many other compounds, such as ferrocyanides, formic acid, oxalic acid, etc. In comparison with other nitrogen-fixation processes, the cyanide process has the advantages of cheapness and reliability. It has the drawback of requiring a slightly higher temperature; in this connexion some experimental investigations appear to indicate that the temperature required is proportional to the melting point, not of the metallic salts as has been stated by some, but of the metals, and that it is inversely proportional to their atomic weights. It may therefore be conjectured that with salts of rubidium and caesium, a working temperature of 600° C. might be practicable.—W. J. W.

Ammonium carbonate; Determination of the partial and total pressures of solutions of — in water, with special reference to ammonia scrubbing and concentration of ammoniacal liquor. E. Terres and H. Weiser. J. Gasbeleucht., 1920, 63, 705–712.

Gas liquor from horizontal retorts contained 20·45% NH_3 , of which 67·82% was present as ammonium carbonate, whilst liquor from vertical retorts contained 16·39% NH_3 , of which 78·83% was present as carbonate. Liquors containing 85–88% of their ammonia as ammonium carbonate are also met with. The partial pressures of water vapour, ammonia, and carbon dioxide in aqueous solutions containing ammonia and carbon dioxide in proportion corresponding to $(\text{NH}_4)_2\text{CO}_3$, were determined by a transpiration method at 20° C., 40° C., 60·8° C., and 80° C., and the values for the respective total pressures deduced from such partial pressures were confirmed at these temperatures by a manometric method, which was likewise applied to determine the total pressure in the solutions at 90° C. and 95° C.

The following results were obtained:—

Concentration of solution. ($\text{NH}_4)_2\text{CO}_3$	Partial pressure (mm. Hg)											
	H_2O				NH_3				CO_2			
	20°	40°	60·8°	80°	20°	40°	60·8°	80°	20°	40°	60·8°	80°
2·82	16·8	55·6	155·0	350·0	1·8	4·8	15·3	38·8	2·7	9·6	53·5	106·0

method of separating atmospheric nitrogen is by the use of spongy iron as an oxygen-absorbent. To avoid choking caused by pulverisation and to promote activity the iron is impregnated with sodium hydroxide and briquetted. The ferric oxide formed may be subsequently reduced either by the carbon

At higher temperatures and also at 80° C. with the 14·1% solution it was not possible to determine the partial pressures, but the total pressures were 854 mm. for the 14·10% solution at 80° C., 695 mm. and 801 mm. for the 2·82% solution at 90° and at 95° C., 842 mm. and 978 mm. for the 5·65% solu-

tion at 90° and 95° C., and 1076 mm. for the 8.46% solution at 90° C. The application of the results to the operations of gas scrubbing and the concentration of ammoniacal liquor is briefly discussed.

—J. S. G. T.

Ammonium salts; Microchemical test for —. C. van Zijp. Pharm. Weekblad, 1920, 57, 1345—1348.

FORMALDEHYDE combines directly with ammonium salts, yielding salts of hexamethylenetetramine, which can be detected by means of iodine-potassium iodide solution. This solution affords an excellent microchemical reagent for ammonium salts after addition of formalin. (Cf. J.C.S., Dec.)—S. I. L.

Iodic acid; Action of very concentrated solutions of — on ammonia gas. G. Denigès and J. Barlot. Bull. Soc. Chim., 1920, 27, 824—825. (Cf. J., 1920, 595 A.)

If a drop of 50% iodic acid is exposed to an atmosphere containing a trace of ammonia gas, it becomes coated with a thin white film, and if this is then well mixed with the acid, rhombic crystals of ammonium tri-iodate can be observed under the microscope. If a drop of 50% iodic acid and a drop of strong ammonia are placed a few mm. apart on a microscope slide, the successive formation of the neutral iodate, the di-iodate, and the tri-iodate may be observed.—W. G.

Cyanic acid; Microchemical detection of —. R. Fosse. Comptes rend., 1920, 171, 722—723.

CYANIC acid precipitated as silver cyanate may be detected by three tests. (1) The silver cyanate when crystallised from hot water is obtained in a definite and characteristic microscopic form. (2) When silver cyanate, potassium chloride, and cobalt acetate are ground together, blue potassium cobaltcyanate is produced; the colour is destroyed by water and restored by alcohol. The cobaltcyanate may be distinguished from the sulphocobaltcyanate in that the latter gives a colour with amyl alcohol or ferric chloride, while the former does not, and the cobaltcyanate is not destroyed nor decolorised by dilute acids. (3) If silver cyanate is ground with hydroxylamine hydrochloride, and the product moistened with a drop of ferric chloride solution, a violet-blue colour is obtained.—W. G.

Sulphur dioxide; Oxidising properties of —. I. Iron chlorides. W. Wardlaw and F. H. Clews. Chem. Soc. Trans., 1920, 117, 1093—1103.

THE oxidation of ferrous chloride by sulphur dioxide is represented by the equation $4\text{FeCl}_2 + \text{SO}_2 + 4\text{HCl} = 4\text{FeCl}_3 + 2\text{H}_2\text{O} + \text{S}$, and as sulphur is able to reduce ferric chloride to a small extent the reaction is apparently reversible. The degree of oxidation by sulphur dioxide is independent of the initial concentration of iron. The optimum temperature in presence of 33% hydrochloric acid is 95° C., and no oxidation at all occurs at this temperature if the concentration of free hydrogen chloride is less than 165 g. per l. The highest percentage of ferric iron obtained in any of the flask experiments recorded was 8.8. This result was obtained by treating ferrous chloride solution in 33% hydrochloric acid at 115° C. with a 50% mixture of sulphur dioxide and hydrogen chloride under special conditions. Sealed tube experiments gave a maximum yield of 9.5% of ferric iron. Iron solutions containing 10—18.3% of ferric iron in 33% hydrochloric acid at 115° C. showed no evidence of oxidation or reduction by sulphur dioxide under the special conditions mentioned above, but when the ferric iron exceeded 18.3% a slow reduction occurred.—G. F. M.

Sulphur dioxide; Oxidising properties of —. II. Iron phosphates. W. Wardlaw, S. R. Carter, and F. H. Clews. Chem. Soc. Trans., 1920, 117, 1241—1247.

THE reaction between sulphur dioxide and iron phosphates in concentrated phosphoric acid solution is solely one of oxidation: $4\text{Fe}(\text{H}_2\text{PO}_4)_2 + 4\text{H}_2\text{PO}_4 + \text{SO}_2 = 4\text{Fe}(\text{H}_2\text{PO}_4)_3 + 2\text{H}_2\text{O} + \text{S}$. The reaction is probably reversible, similarly to that of sulphur dioxide with ferrous chloride (cf. *supra*), but it is considerably modified by the formation of the complex compound which ferric phosphate forms with phosphoric acid. This may account for the much higher yield of ferric salt from a pure ferrous phosphate solution than from a ferrous chloride solution, and may also explain the non-reducibility of ferric phosphate in phosphoric acid solution by sulphur. The limiting concentration of phosphoric acid below which oxidation by sulphur dioxide does not take place is about 332 g. of "free" acid per l. at 100° C. The authors seek to correlate the oxidising and reducing action of sulphur dioxide in strong and dilute acid media respectively by an explanation on an ionic basis.—G. F. M.

Phosphates or arsenates; Sensitive colour test for —. G. Denigès. Comptes rend., 1920, 171, 802—804.

THE reagent used is a mixture of equal volumes of a 10% solution of ammonium molybdate and concentrated sulphuric acid. From 3 to 10 drops of the reagent are added to the solution to be tested, the mixture is shaken, and one or two drops of a freshly prepared solution of stannous chloride are added. The solution develops a blue colour if phosphates or arsenates are present. Fluorides tend to inhibit the reaction, but this can be overcome by the preliminary addition of boric acid if they are present. The reaction is given in the presence of organic matter.—W. G.

Thermochemical analysis of solutions. [Detecting formation of double salts.] Chauvenet, P. Job, and G. Urbain. Comptes rend., 1920, 171, 855—857.

THE method used is similar to that of Dubrisay (J., 1920, 542 A) and by its use the existence of the following double salts is indicated: $2\text{KCl} \cdot \text{CaH}_2$, $2\text{CuCl}_2 \cdot 3\text{MgCl}_2$, $3\text{CuCl}_2 \cdot 2\text{MgCl}_2$, $2\text{CuCl}_2 \cdot 3\text{CaCl}_2$, $\text{CuCl}_2 \cdot \text{CaCl}_2$, $\text{CuCl}_2 \cdot 2\text{AlCl}_3$, and $2\text{CuCl}_2 \cdot \text{AlCl}_3$.—W. G.

Hydrous oxides. I. Hydrous ferric oxide. II. Hydrous aluminium oxide. H. B. Weiser. J. Phys. Chem., 1920, 42, 277—328, 505—538.

THE existence of a definite basic ferric salt has not been established with certainty, and only one definite crystalline hydrate of ferric oxide has been prepared. It is probable that the different ferric iron colloids are not composed of basic salts of varying composition or of hydrous hydrated oxides, but are hydrous ferric oxides. The difference in properties of colloidal hydrous ferric oxides prepared by different methods and of different ages is due to a difference in the degree of hydration and in the size of the colloidal particles. Certain electrolytes precipitate the Péan de St. Gilles colloid (Comptes rend., 1855, 40, 568, 1243) in a gelatinous form whilst others precipitate it in a granular form. The most gelatinous precipitate is obtained when there is very rapid aggregation of the hydrous particles throughout the entire solution and when the electrolyte present exerts no solvent action; the most granular precipitate results when the agglomeration proceeds slowly and when the electrolyte possesses a solvent action. Hydrochloric acid has two precipitating values for the Péan de St. Gilles colloid, one above the other with a zone of non-precipitation between, in which

the colloid is less stable than the original colloid. The degree of reversibility of the precipitation of hydrous ferric oxide is determined mostly by the specific adsorbability of the precipitating ion, although the physical character of the precipitate has an influence. It is possible to make a transition from brown to yellow hydrous ferric oxide by increasing the size of the particles, e.g., by heating water to which ferric chloride has been added. The yellow colloidal hydrous oxide is not readily dehydrated at 100° C., and probably contains adsorbed ferric salt. A yellow colloidal solution was prepared by the Péan de St. Gilles method by allowing the acetate solution to stand for a few days before diluting and boiling. The slow hydrolysis of the acetate favours the formation of yellow hydrous oxide stabilised by adsorbed ferric salt. When the solution is boiled, a stable yellow colloid is formed instead of the usual brick-red one.

Aluminium oxide forms only one definite hydrate, the trihydrate, precipitated from solutions of the oxide in alkali. The so-called hydrates formed by precipitating with ammonia are hydrous oxides. Any number of hydrous oxides, similar to those of ferric oxide, may be prepared, differing in size of particles and amount of water. The larger and less hydrous the particles, the less soluble are they in acids and alkalis. There is no definite temperature of inversion from soluble oxide to insoluble meta-oxide. The colloidal oxide prepared by prolonged digestion of aluminium acetate at high temperature is insoluble in acids and alkalis, and has no mordanting action; the colloid prepared by peptising gelatinous alumina with aluminium chloride and dialysing in the cold is soluble in acids and alkalis, and possesses a mordanting action. Colloids with intermediate properties may be obtained. Colloidal alumina is a positive colloid, and is stabilised by preferential adsorption of cations. The relative peptising power at 100° C. was found to be in the order: nitric acid > hydrochloric acid > ferric chloride > aluminium chloride > acetic acid. Strong acids with univalent anions and their salts precipitate colloidal alumina only at high concentrations and the reaction is reversible. Acids with multivalent anions and their salts precipitate the colloid at low concentrations and irreversibly. Gelatinous alumina dissolves in sodium or potassium hydroxide with the production of an unstable aluminate, from which colloidal hydrated alumina separates in a granular, difficultly soluble form. Observation of the effect of the nature of the coagulating agent on the physical character of the precipitated oxide confirmed the conclusions reached with ferric oxide.—J. R. P.

Occlusion of hydrogen by palladium; Influence of hydrogen sulphide on the —. II. E. B. Maxted. Chem. Soc. Trans., 1920, 117, 1280—1288.

The inhibitive effect of hydrogen sulphide on the occlusive power of palladium for hydrogen is a linear function of the concentration of hydrogen sulphide, the critical value for complete inhibition being about 8.5 c.c. of hydrogen sulphide per g. of palladium. The primary absorption of hydrogen is followed in all cases by a slow secondary occlusion which gradually increases in velocity and finally slows down again as the limit of total occlusion is approached. This secondary occlusion appears to be due to the slow spontaneous dissociation of the absorbed hydrogen sulphide, a change which has already been shown to take place instantaneously at 100° C., the sulphur being retained by the palladium as a Pd₂S complex, which is itself incapable of occlusion, but leaves the residual palladium with its normal occlusive power for hydrogen. The hydrogen liberated by this dissociation is equal in volume to the hydrogen sulphide dis-

sociated, and must be added to the observed volume of hydrogen absorbed to arrive at the true occlusive power of the preparation. Confirmation of the above theory is found in the fact that the total volume of hydrogen thus found to be contained in samples of palladium previously treated with varying amounts of hydrogen sulphide falls on the known poisoning curve, calculated on the basis of the presence of the Pd₂S complex in amount equivalent to the sulphur contained in the hydrogen sulphide occluded.—G. F. M.

Sulphur dioxide in gases from roasting low-grade ores; Process for increasing the concentration of —. H. Petersen. G.P. 310,073, 15.3.18.

DURING the roasting of ores, poor in sulphur, by means of furnace gases, only so much air, which may be previously heated, is introduced into the furnace as is required to attain the desired temperature.—W. J. W.

Sulphuric acid from copper matte; Process for obtaining —. Metallbank und Metallurgische Ges. A.-G. G.P. 310,621, 10.4.18.

FUSED copper matte is passed in a continuous stream into a converter, which is provided with means for collecting the sulphur dioxide evolved and conducting it to a sulphuric acid plant. The oxidised copper matte and slag are removed continuously at the same rate as fresh matte is introduced.—W. J. W.

Nitrogen oxides; Apparatus for the catalytic preparation of — from ammonia and air. S. Barth. G.P. (A) 298,951, 31.7.15, and (B) 310,352, 21.11.15.

(A) THE apparatus consists of a revolving drum with cylindrical sieve-like walls which act as the catalyst, arranged in a closed receptacle fitted with two tubes through which the gas enters and leaves the apparatus. The former tube contains a valve and terminates in a perforated porcelain tube arranged along the axis of the drum above the other tube, which is set in the floor. (B) The catalyst is built up between a fine network of aluminium wires which act as a cooling medium and prevent decomposition of the gases either before or after passing through the catalyst.—A. R. P.

Fixation of nitrogen; Process and apparatus for the electrical — from air and the products resulting therefrom. J. E. Bloom. U.S.P. 1,334,590, 23.3.20. Appl., 21.8.18.

IN the fixation of atmospheric nitrogen by means of the electric arc, an earthing electrode is provided in the path of the gases near the arc and is connected with the earth through an insulated ground line and an insulated "interrupter-selector" adapted to pass to the earth only one kind of charge, electron, or the like. The gases leaving the arc are passed rapidly through successive alternating current fields beyond the arc furnace, then through absorption towers or chambers containing masses of comminuted solid absorption material (corundum, silica, etc.) at progressively reduced temperatures down to 50° C. The gases are finally passed through absorption towers supplied with sprays of water or alkaline solution and provided

with electrodes instead of the usual plates. Alternating current fields are created in the absorption tubes or chambers and in the absorption towers.

—B. N.

Combustion of nitrogen; Process for —. *Gewerkschaft des Steinkohlenbergwerks "Lothringen,"* and M. Kelting. G.P. 324,261, 23.7.19.

IN the combustion of nitrogen in a hydrogen or carbon monoxide flame, the yield of nitrogen compounds is appreciably increased by introducing 1—2% of solid carbon or carbon compounds of high melting point, so as to produce finely-divided incandescent carbon in the flame.—W. J. W.

Alkali percarbonates; Manufacture of —. H. Wade. From Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler. E.P. 152,366, 20.8.17.

CALCINED alkali carbonates are treated with hydrogen peroxide solution to which common salt has been added, preferably in presence of anti-catalysts, such as sodium silicate, magnesium chloride, or magnesium-sodium silicate. A yield of 90% of solid alkali percarbonate is obtainable.—W. J. W.

Magnesium chloride or double chlorides of magnesium; Production of anhydrous —. E. A. Ashcroft. E.P. 152,401, 9.7.19.

MAGNESIUM chloride in the form of needle crystals is subjected to the action of a current of heated air by which it becomes partially dehydrated, and its m.p. is raised to about 250° C., without the salt undergoing decomposition. It is then transferred to another apparatus in which, by the action of a current of hydrogen chloride the remaining water of crystallisation is removed, the temperature being slowly raised to 650° C. during the process. The product contains at least 98% of pure anhydrous magnesium chloride, and the hydrogen chloride is recovered by condensation as a 33% solution. Double salts of magnesium chloride may be similarly treated, with slight modifications of temperature.—W. J. W.

Arsenious acid; Process for refining —. M. Uchino. E.P. 152,526, 27.10.19

ARSENIOUS acid may be refined by adding to it copper oxide, or a mixture of oxides of copper and iron, and then distilling.—W. J. W.

Acetates, etc.; Production of — [from carbohydrates]. J. W. H. Randall, Assr. to Industrial Chemical Co. U.S.P. 1,338,040, 27.4.20. Appl., 27.6.17.

CARBOHYDRATES, such as sugar, starch, cellulose, gum, etc., are dissolved in, or mixed with, caustic alkali solution, the mixture is concentrated, mixed with sufficient quicklime to form a dry, porous mass, and heated to 250°–300° C. with exclusion of air.

Titanium and vanadium compounds; Process for recovering —, or either, from minerals containing them together with iron. B. P. F. Kjellberg. G.P. 324,581, 17.10.19. Conv., 24.2.19.

THE mineral is dissolved in a suitable solvent, the solution evaporated to dryness, and, if titanium is present, the residue is heated without decomposition, treated with water, and the solution heated. The precipitated titanium compound is separated, the solution evaporated, and the residue heated to convert the iron into insoluble oxide. If vanadium is present the product is then dissolved in a suitable solvent to extract the soluble vanadium compounds. Special methods are given for treatment of ores containing only iron and vanadium, or, in addition, very small amounts of titanium.—W. J. W.

Carbon dioxide; Process of recovering — from gases. Deutsche Oxydrie A.-G. G.P. 324,868, 3.6.19.

CARBON dioxide is removed from gases containing it by absorption in water under pressure, from which it is recovered by passing the water into a vacuum chamber. The exhaust water is used first to cool the compressor employed in the first operation, then to wash further quantities of gases before compression.—A. R. P.

Furnace for the production of sulphates from bisulphates. Verein Chem. Fabr. in Mannheim. G.P. 325,314, 18.6.16.

THE iron muffle, in which the bisulphate is heated with a reducing agent or with rock salt, is charged by means of a worm screw so arranged that the charge is preheated and thoroughly mixed.

—L. A. C.

Ammonia and hydrogen sulphide; Removing — from gases or vapours containing less hydrogen sulphide than ammonia. W. Feld, Gasabteilung, G.m.b.H. G.P. 325,652, 9.8.18.

THE gas is washed with a thionate solution which is used continuously without regeneration, but to which a little regenerated solution is added as required. Hydrogen sulphide only is thus removed, and the gas is then passed through sulphuric acid to recover the ammonia as ammonium sulphate.

—L. A. C.

Hydrogen; Process for production of —. C. Toniolo, and Officine Elettrochim. Rossi. E.P. 152,554, 5.1.20. Conv., 29.10.19.

OXIDES of iron, or of alkali or alkaline-earth metals, or of mixtures of these, are reduced by means of gases from smelting furnaces, or from blast furnaces fed with oxygen. The free metals or their lower oxides are then treated with water vapour, by which means the original oxides are reproduced and hydrogen is formed.—W. J. W.

Supersaturated solutions of oxygen; Manufacture of — from per-salts and catalysts. M. Sarason. G.P. 325,155, 21.5.16.

SOLUTIONS of perphosphates, e.g., pyrophosphates, are used, such solutions being considerably more stable than those of perborates.—L. A. C.

Sulphur; Process for separation of — from gases obtained in the roasting and smelting of sulphur-bearing ores. C. G. Collins. E.P. 152,447, 22.7.19.

SEE U.S.P. 1,314,631 of 1919; J., 1919, 861A. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 1974 of 1881 and 6567 of 1892.)

Acid-proof alloys. E.P. 121,730. See X.

Magnesium chloride. E.P. 152,403. See X.

VIII.—GLASS ; CERAMICS.

Glasses; Density of soda-magnesia —. C. J. Peddle. J. Soc. Glass Tech., 1920, 4, 281–283.

IN glasses of the type $x\text{Na}_2\text{O} \cdot y\text{MgO} \cdot 5\text{SiO}_2$, the density falls proportionately as the Na_2O is replaced molecularly by MgO . English and Turner (J., 1920, 627A) have found that in glasses of a similar type but with 6SiO_2 , the same change occurs. As the latter glasses have a lower density for the same content of soda and magnesia, the addition of silica must lower the density. When the silica remains constant, the replacement of 1 mol. Na_2O by 1 mol.

CaO increases the density, whilst the substitution of 1 mol. MgO for 1 mol. Na₂O decreases it, so that 1 mol. Na₂O added to a glass of this type has a greater effect than the addition of 1 mol. MgO, but a smaller effect than 1 mol. CaO.—A. B. S.

Glass; Surface effects on — probably produced by reheating in the glory-hole. M. W. Travers. J. Soc. Glass Tech., 1920, 4, 284—286.

SPECIMENS of microscope slides and photographic plates were scratched on one surface and apparently pitted on the other, the apparent pitting being in the form of minute bubbles, 0.001 mm. diameter, immediately below the surface. The author suggests that the pitting was caused by the evolution of gas when the ball was reheated in the glory-hole before blowing the cylinder from which the slides and plates were made, and that the scratches were formed on the surface which was inside the cylinder by the wooden block used in the flattening process. The "sulphuring" of lead glass may be due to a similar cause.—A. B. S.

Glass; Expansion of — at high temperatures. W. B. Pietenpol. Chem. and Met. Eng., 1920, 23, 876—877.

THE EXPANSION of various kinds of glass was measured from ordinary temperatures up to 750° C. and the results plotted. The rate of expansion of annealed glass is nearly linear up to 450°—550° C.; it then increases by 4—6 times for the next 60°—100° C., after which it again becomes linear until the softening point is reached, when it gradually decreases until the glass loses its form. With unannealed glass the rate of expansion at first decreases due to the relieving of the internal strain, then the glass behaves as annealed glass except that on cooling shrinkage takes place in amount depending on the strain which has been relieved.—A. R. P.

Plastic substances [glass]. Le Chatelier. See X.

PATENTS.

Glass capillary tubes; Process for manufacturing — of a prescribed interior form. K. Küppers. G.P. 306,004, 25.7.16.

A TUBE of approximately the correct size is pulled over a metal wire of the exact size required, then heated sufficiently, but without melting, so that it acquires the correct size. After cooling, the wire is partly dissolved by forcing acids or, in the case of nickel, carbon monoxide between the wire and the glass until the wire is so thin that it can readily be pulled out.—A. R. P.

Drying apparatus [for bricks etc.]. O. Imray. From F. A. Secord, C. H. Peters, and A. P. Paterson. E.P. 152,505, 1.10.19.

THE BRICKS or other plastic material to be dried are placed on hollow supports which are perforated for the passage of drying gases and supported on a truck, or other means of conveyance, in such a manner that any support (above the lowest) may be swung aside to permit access to the bricks on the next lower support without allowing the escape of drying fluid. The drying fluid is preferably supplied through a conduit supplying several supports, to which it is connected by detachable headers, and the supply may be cut off from any support at will.—B. M. V.

Gas fired ring furnaces; Process and apparatus for firing at high temperatures in —. J. Schmelz. G.P. 319,698, 13.4.19.

THE FURNACE consists of two series of parallel chambers joined to each other and heated one after the other in the same direction by a common regenerator, while the preheating chamber is fired with gas and preheated air from the cooling

chamber. In this way a temperature sufficiently high to fire refractory materials, such as magnesite, Dinas brick, etc., is rapidly and economically obtained.—A. R. P.

Bricks; Process for preparing dry-pressed — from clay. Chem. Lab. für Tonind. und Tonind.-Zeit. H. Seger und E. Kramer G.m.b.H. G.P. 324,189, 26.10.15. Addn. to 321,930 (J., 1920, 690 A).

THE BRICKS are made from clay, part of which has been heated above the usual drying temperature to render it non-plastic and the remainder of which is raw clay. The mixture still has a certain plasticity.—A. R. P.

Lithographic stones; Manufacture of artificial —. J. Kiermayer, and Vercin. Chem. Fabr. zu Leopoldshall A.-G. G.P. 324,222, 26.6.19.

ARTIFICIAL lithographic stones are prepared from mixtures of magnesium oxide obtained by heating magnesium chloride to redness, and magnesium chloride solution of 15°—35° B. (sp. gr. 1.116—1.320).—W. J. W.

Plastic masses from fine powders and colloidal solutions; Process for producing —. E. Podszus. G.P. 325,307, 4.2.14.

PRECIPITANTS such as tannic acid, gelatin, or the like, or oppositely charged colloids are added, in quantity nearly sufficient to produce precipitation, to solutions of colloids, such as silicic acid, which are precipitated with difficulty by means of electrolytes. When moulds other than plaster moulds are used for shaping the mixture of colloidal solution and fine powder, they are first impregnated with salts capable of precipitating the colloid. By these means precipitation of the colloid at the surface of the mould is facilitated.—L. A. C.

Kilns. C. H. Zwermann. E.P. 140,740, 29.9.19. Conv., 27.3.19.

IX.—BUILDING MATERIALS.

Cement; Influence of additions of calcium sulphate or chloride on the shrinkage of —. A. Guttmann. Zement, 1920, 9, 310—313, 429—432. Chem. Zentr., 1920, 91, IV., 527—528.

ADDITION of raw gypsum or calcium chloride to Portland, iron-Portland, or blast-furnace cement causes them to swell so that the natural shrinkage is counteracted or only takes place after a long time. Cements so treated are especially adapted for use as mortars where it is desired that the joint should be nearly invisible.—A. R. P.

Wood preservation. Moll. See XIXb.

PATENTS.

Porous material [from slag]; Manufacture of —. Det Norske Aktieselskab for Elektrokemisk Ind. Norsk Ind.-Hypotekbank. E.P. 136,818, 15.12.19. Conv., 16.12.18.

MATERIAL of uniform porosity suitable for building or insulating purposes is produced by passing water, with or without the addition of steam or other gases, into slag at about 1400° C., stirring until a foam is formed, and drawing off the foam into moulds to cool.—L. A. C.

Cement; Manufacture of — from slag. R. Boveroulle. E.P. 149,988, 9.8.20. Conv., 7.8.19.

In the manufacture of slag cement by the cold process, lime cinder or dross is used instead of fat (or white) lime or hydraulic lime in stone form.

—L. A. C.

Cement; Process for burning — in shaft furnaces. Fellner und Ziegler. G.P. 320,731, 30.11.18.

WATER is sprayed into the discharging hopper of the furnace so as to precipitate dust that would otherwise be blown out, and to quench any incompletely sintered material. In this way a certain amount of steam is produced which, together with air, is drawn into the furnace and exerts a beneficial effect on the calcining operation.—A. R. P.

Light building materials; Utilisation of the residues from burning bituminous shales in the preparation of —. Rekord-Zement-Ind. G.m.b.H. G.P. 324,637, 25.9.17.

THE finely powdered or slimed residues are mixed with a light filling material, and the mixture is moulded and burnt, with or without the addition of clay. Alternatively, the finely powdered material may be mixed with the necessary binding and hardening substances and the moulded articles prepared from this mixture in a known manner.—A. R. P.

Rough sand for industrial uses; Manufacture of —. H. Stoltzenberg. G.P. 325,613, 1.7.19.

SAND for use, e.g., for admixture with clay, lime, cement, tar, or the like, is treated with hydrogen fluoride gas or with salts of hydrofluoric acid, such as ammonium fluoride, which dissociate when vaporized. The treatment is carried out, e.g., in heated drums, and has the effect of pitting the surface of the sand.—L. A. C.

Colouring wood grey or black; Process for —. R. E. Slade. E.P. 152,427, 14.7.19.

WOOD is impregnated separately under a pressure of 60–300 lb. per sq. in. with solutions of an iron salt and tannin and/or logwood extract, and subsequently with a solution of lime water or ammonia. Before treatment and after each impregnation the wood is dried under reduced pressure with or without the aid of heat.—L. A. C.

Wood; Process for artificial seasoning of —. M. Kleinstück. G.P. 323,973, 30.10.14.

WOOD is first dried in a vacuum, and then treated warm with a mixture of oxygen, ozone, or air, and catalysts such as ammonia, methylamine, or dimethylamine, or the products obtained by interaction of ammonia and formaldehyde.—W. J. W.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Blast furnace; Effect of temperature, pressure, and moisture of the air upon the working of the —. A. Wagner. Stahl u. Eisen, 1920, 40, 1397–1403.

THE theoretical effects of temperature, pressure, and moisture of atmospheric air on its weight were calculated according to the mechanical theory of heat, utilising the average highest and lowest values of these variables issued for a period of twelve months from a meteorological station. Graphical representations of the working results from a Rhenish blast furnace plant indicate that for given blowing power, the lowest blast pressure and the greatest production were attained during the month of May, in which the air weight per cb. m. was below the average value. Coke consumption was not affected by the moisture of the air and for practical purposes varied inversely with

the yield of iron from the ore. Further work is necessary to determine whether blast regulation according to the weight of the air or according to pressure exerts the better influence on output.

—J. W. D.

Steel manufacture; New deoxidisers for —. J. R. Cain. Chem. and Met. Eng., 1920, 23, 879–882.

WITH the idea of finding a new alloy of two or three of the metals manganese, silicon, titanium, aluminium, which, when used as a deoxidiser for steel would give a very fusible slag, the melting points in the systems, manganese oxide—silica, manganese oxide—titanium oxide, manganese oxide—silica—alumina, manganese oxide—silica—titanium oxide, and manganese oxide—alumina—titanium oxide were determined. The results indicate that the alloys which may be expected to give the most fusible slags are: 75 Mn, 24 Si, oxides melt at 1228° C.; 41% Mn, 59 Ti, oxides melt at 1160° C.; 49% Mn, 18% Ti, 33 Si, oxides melt at 1130° C.; 13% Al, 52% Mn, 35% Si, oxides melt at 1121° C.; 12% Al, 47% Mn, 41 Ti, oxides melt at 1320° C.—A. R. P.

Steel; Woody fibrous fracture in —. E. H. Schulz and J. Goebel. Stahl u. Eisen, 1920, 44, 1479–1485.

SEVERAL different type fractures of rolled and pressed steel showing woody fibre structure were investigated, and it was found that this phenomenon may be due to widely different causes. The fractures may be divided into two principal groups. The first type is due to separation of material in the unbroken rods, which may be due to piping, inclusion of extraneous metal which has got into the mould without dissolving in the fluid steel, and blowholes, or to slag inclusions and segregation which produce regions of low tenacity. The cause of the second type has not yet been fully explained but is possibly connected with stresses occurring in the material. In some cases the fibrous structure may be removed by annealing at 600° C., in others annealing has no effect.—T. H. Bu.

Graphite and temper carbon obtained from cast iron; Crystalline nature of —. K. Iokibe. Sci. Rep. Tōhoku Imp. Univ., 1920, 9, 275–279.

THE diffraction figures produced by X-rays on compressed cylinders of graphite electrolytically separated from grey cast iron and temper carbon isolated from an annealed white cast iron show that these two forms of carbon are identical with natural graphite. Sugar carbon having no crystalline structure did not show diffraction rings.

—T. H. Bu.

Carbon steels quenched and tempered; State of the carbide in —. S. Saitō. Sci. Rep. Tōhoku Imp. Univ., 1920, 9, 281–287.

SPECIMENS of six carbon steels with carbon varying from 0.5 to 1.95% and of a white cast iron were heated in a vacuum and examined by the magnetometric method. When a quenched steel is tempered cementite separates from solid solution at 288° C. Immediately above this point the greater part readily decomposes into iron and carbon owing to the fineness of its particles. Up to 350° C. re-combination goes on and the magnetisation slightly decreases. Large-grain coagulated cementite corresponding to microstructures ranging from sorbite to pearlite is not decomposed to an appreciable extent below A1. In hypereutectoid steels above the A₁ point some free cementite exists which is partially decomposed into iron and carbon at these high temperatures. Free carbon when dissolved in iron at high temperatures combines to form cementite and during cooling is set free as combined carbon. The atomic configuration

corresponding to the solution of cementite or carbon atoms in austenite is the same. Observations on hypoeutectoid steels are in accordance with the above views.—T. H. Bu.

Steel; Critical heat treatment after critical cold work of a low carbon —. A. Pomp. Stahl u. Eisen, 1920, 40, 1261–1269, 1366–1378, 1403–1415.

A soft steel containing C 0.05%, Mn 0.10%, Si trace, P 0.005%, S 0.035%, Cu 0.024%, and giving the following tests after normalisation at 1000° C., hardness 89, yield point 23.1 kg. per sq. mm., tensile strength 31.2 kg. per sq. mm., elongation 31%, notched bar test 20.3 m.-kg. per sq. cm., was rolled at various temperatures up to the Ar3 temperature, and then annealed at temperatures between 650° and 850° C. Marked grain growth, corresponding to an increase of 22,000–34,000% over the original size, occurred when the reduction in section was between 8 and 16%, being most pronounced at about 11%. At the same time the hardness decreased 9–14%, the yield point 35–47%, the tensile strength 4–11%, and the notched bar test 84–93%, while the elongation increased 9–25%. The reduction in area did not undergo a regular change. Within the limits of critical cold work, 8–16%, divorce of the pearlite occurred, the freed cementite separating in the state of fine threads at the ferrite grain boundaries.—J. W. D.

Steels; The Ar3 point of — and martensite. P. Dejean. Comptes rend., 1920, 171, 791–794.

A REVIEW of the author's previous work (cf. J., 1917, 965) in the light of recent work by Chevenard (cf. Guillet, Rev. gén. Sci., 1920, 31, 1496).—W. G.

Arc-fused steel; Metallography of —. H. S. Rawdon, E. C. Groesbeck, and L. Jordan. Chem. and Met. Eng., 1920, 23, 777–784. (Cf. J., 1920, 752 A.)

ARC-FUSED steel shows characteristic globules of oxide which coalesce to larger globules on annealing; it also shows needles or plates which are probably due to nitrides, as a similar structure is shown by iron which has been nitrogenised. The nitrogen content of the steel after fusion in the arc is considerably increased, whereas most of the other impurities present are burnt out. The nitride plates gradually disappear both from arc-fused and nitrogenised metal on annealing at 1000°–1200° C. *in vacuo*. Thermal analysis of specimens of steel before and after arc fusion showed that the Ar3 and Ac3 points are depressed about 50° C. by the fusion, whereas the Ac2 and Ar2 points are unaffected. Microscopical examination shows that the arc-fused metal is inherently ductile, but that other imperfections mask this quality. The use of a protective coating on the electrodes during welding does not appear to affect the mechanical properties of the weld in any way.—A. R. P.

Plastic substances [steel, glass]; Mechanical properties of —. Importance of reactivity. H. and F. Le Chatelier. Comptes rend., 1920, 171, 695–699.

From the results of torsion tests on glass at its temperature of annealing (540° C.), and on mild steel at its temperature of forging (825° C.), it is shown that at a sufficiently high temperature, and with small forces, plastic substances undergo successively three types of deformation:—(1) An instantaneous elastic deformation which disappears immediately after the suppression of the force; (2) a subpermanent deformation, produced slowly and disappearing slowly after the suppression of the force, and having an order of magnitude comparable with that of the instantaneous deformation; (3) a viscous deformation continuing the subperma-

nent deformation; this is produced with a constant velocity and does not disappear after the suppression of the force. In the case of soft steels Coulomb's modulus of elasticity is probably a linear function of the temperature.—W. G.

Metal [silicon-iron] tubes unattacked by steam at temperatures above 1000° C. P. Askenasy. Z. Elektrochem., 1920, 26, 436.

TUBES made from silicon-iron (as used in the construction of dynamos) are very little attacked by air or mixtures of steam and oxygen at temperatures up to 1100° C. The metal is brittle, but by careful heating may be raised to a dull red heat and can then be bent into a tube which may be autogenously welded. Such tubes when encased by cast iron serve well as superheaters for steam. Chromium-nickel tubes are equally resistant to steam at high temperatures.—J. F. S.

Carbon-manganese alloys; Equilibrium diagram of —. K. Kido. Sci. Rep. Tôhoku Imp. Univ., 1920, 9, 305–310.

THE author has modified and completed the equilibrium diagram of manganese and carbon established by Stadelher (J., 1908, 572). In the solid state manganese carbide (Mn₃C) and carbon are only partially soluble in each other. As the temperature falls the solubility of both decreases and they form a eutectoid containing about 3.7% C. Microscopical examination of specimens quenched at different temperatures indicated the eutectoid temperature to be 930° C. on heating and 830° C. on cooling. This was confirmed by thermal analysis. (Cf. J.C.S., Dec.)—T. H. Bu.

Zinc dust; Influence of foreign gases on the formation of — during the condensation of zinc vapours. O. Ravner. Tekn. Ukeblad, 1920, 67, 404–408, 418–420. Chem.-Zeit., 1920, 44, Rep., 256.

IN order to minimise the deposition of zinc dust during the condensation of zinc vapours the following points should be observed. The temperature of the receiver should be a little above the melting point of zinc and the distance between the retort and the receiver should be as small as possible, as the longer the time that elapses before the vapours condense the greater is the amount of carbon dioxide formed by decomposition of the carbon monoxide present. This leads to the formation of films of zinc oxide on the droplets of condensed zinc, and prevents them running together. Similar effects are obtained if nitride is formed, either from nitrogen in the coke or from leakage of air into the retort; or if the ore or fuel contains sulphur, zinc sulphide being slightly volatile. Traces of moisture in the charge lead to the formation of dust in the pipes, and, in general, the more the zinc vapours are diluted with foreign gases the greater is the dust deposit. Chemical and screen analyses are given of typical coarse and fine zinc dust. In order to obtain a metallic regulus from the dust the best process is to melt it with a mixture of equal parts of zinc and calcium chlorides; in one case a yield of 91% of the total metal present was obtained in this way.—A. R. P.

[Copper-aluminium] alloy; Experiments in manufacturing No. 12 —. R. J. Anderson. Chem. and Met. Eng., 1920, 23, 883–887.

FROM a series of experiments in which No. 12 alloy (Cu 8%, Al 92%) was made by mixing the elements in various manners and observing the dross losses, gas consumption, and microstructure of the resulting castings, the following conclusions were arrived at:—When small quantities of the alloy are being prepared it is sufficient to add light copper sheet to molten aluminium, but for large-scale work it is preferable to add the copper as a rich alloy with

aluminium. The most convenient alloy to employ is that containing equal parts of the two elements, and it should be charged into the furnace at the same time as the aluminium.—A. R. P.

Electrode processes. Influence of rise of temperature and of depolarisers on the form in which nickel separates. H. Stäger. *Helv. Chim. Acta*, 1920, 3, 581—613.

RESULTS are given of investigations on the formation or alteration of deposits of nickel under conditions effecting the depression of the polarisation, and on the behaviour of these deposits when the development of the film of hydrogen, regarded as the true cause of the highly disperse metallic deposits, is suppressed by means of cathodic polarisers. (Cf. J.C.S., Dec.)—T. H. P.

Flotation; Effect of addition agents in —. Part II. M. H. Thornberry and H. T. Maun. *Bull. School of Mines and Met., Univ. Missouri*, 1919, 5, 1—68. (Cf. J., 1918, 93 A, 153 A.)

A CONTINUATION of previous work on the effect of the addition of various salts during the flotation of a lead slime. This part deals with the effect of chlorides, acetates, oxalates, chromates, carbonates, permanganates, tartrates, phosphates, and a few other salts. Tables are given showing the extraction and grade of concentrate obtained with varying quantities of each addition agent. Chromates had a pronounced detrimental effect on both the extraction and grade of concentrate.—A. R. P.

PATENTS.

Casting [steel] ingots. A. V. Carlsson. E.P. 135,207, 13.11.19. Conv., 14.11.18.

THE runner opening or "dead-head" of the mould is rammed with a material, e.g., charcoal breeze, which will burn or evolve heat under the influence of the cast metal. The heat thus liberated is transferred to the upper part of the ingot and prevents or reduces the formation of pipes.

Iron and steel; Extraction of — from ore, and the formation of alloys thereof. T. Rouse. E.P. 152,073, 2.7.19.

FINELY divided ore is mixed or agglomerated with the requisite amount of a ferro-boro-silicate (a concentrated silicate solution containing 3—4% Fe₂O₃ and 5—8% of calcined borax) and reduced to metal in a plant comprising a Siemens furnace provided with electrodes of high conductivity of an alternating three-phase system, so arranged and operated that the initial or heating stages of the process are effected by the gas furnace and the subsequent treatment by the heating action of the three-phase current. Alloying metals may be added at a suitable stage of the process.—J. W. D.

Steel; Manufacture of —. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 152,371, 5.6.18.

STEELS containing either niobium 6—12%, or niobium 3—6% and tungsten 6—10%, or niobium 2—4%, tantalum 3—6%, and tungsten 4—8% are claimed. Niobium has a greater hardening and toughening effect than other alloying metals, and also has a marked purifying action.—J. W. D.

Chrome iron or chrome steel alloys; Production of —. W. B. Ballantine. E.P. 152,399, 9.7 and 16.8.19.

CHROMIUM for the production of chrome-iron or chrome steel alloys is prepared from a thermo-reaction mixture comprising chromic oxide or a mineral containing it, calcium carbide, and a basic oxide, e.g., calcium or barium oxide, with or without one or more other thermo-reducing agents, such as calcium silicide or aluminium.—J. W. D.

Steel or other magnetic materials; Apparatus for detecting the temperature of demagnetisation of —. C. W. Stopford and C. R. Darling. E.P. 152,501, 23.9.19.

A SOFT-IRON rod pivoted inside a coil of wire moves under the increase of magnetic flux due to the steel under treatment and thereby breaks the circuit of a bell or other indicating device. When the temperature of demagnetisation of the steel is reached the soft-iron rod returns to its original position, the circuit is restored, and an indication is given.

Silicon-iron alloys; Prevention of graphite precipitation in the manufacture of acid-resistant —. Maschinenfabrik Esslingen. G.P. 324,267, 4.9.18. Addn. to 306,001 (J., 1918, 628 A).

FERROSILICON is melted with low-carbon iron in the same apparatus, under such conditions as to exclude introduction of further quantities of carbon. —W. J. W.

Steel castings; Process for manufacturing —. H. Hanemann. G.P. 325,571, 23.12.19.

AIR-HARDENING steel is used in the manufacture of the castings, which are then treated in a known manner. Steels with a high tungsten, nickel, or manganese content and a corresponding carbon content have on air-cooling an austenitic and martensitic structure. If such steels are heated a great improvement of the structure takes place, due to the formation of sorbite and granular pearlite, so that the effect of the casting disappears. The whole of the cementite in the steel can be made to agglomerate into nodules by a special heat treatment, e.g., annealing at 500°—700° C. after cooling, reheating the steel and allowing it to cool in the air, followed, if necessary, by a further annealing. —A. R. P.

Electric arc furnaces [for treatment of steel]. A. P. Heyen. E.P. 152,176, 30.8.19.

AN electric arc furnace for the treatment of steel is provided with hollow electrodes enclosing burner tubes through which is introduced into the space above the molten charge a mixture of air and heavy hydrocarbons, whereby the length of the arc is increased.—J. S. G. T.

Electric [metallurgical] furnaces. Electro-Metals, Ltd., and T. D. Robertson. E.P. 152,145, 18.7.19.

IN electric furnaces of the type wherein the current passes from one or more electrodes above the charge, through the latter and by way of a conducting hearth to electrodes embedded therein, escape of molten metal through interstices in the hearth is prevented by surrounding the latter with a non-conducting envelope extending above the highest level of the molten charge. This envelope is contained within a metal casing through which pass one or more metallic conductors extending from below the hearth to a level within the envelope above that of the charge.—J. S. G. T.

Acid-proof metal alloy; Production of an —. C. Rossi. E.P. 121,730, 13.12.18.

AN alloy containing 13—15% Si for ensuring resistance to chlorine and to nitric, sulphuric, and acetic acids, or 20—21% Si for ensuring resistance to hydrochloric acid, is prepared by melting iron and silicon together in an electric furnace and removing all impurities by crystallisation by cooling to not below 1400° C. The strength of the alloy is improved by addition of small proportions of fluxes, such as iron sulphide.—J. W. D.

Alloy. B. A. Bangertter. E.P. 152,277, 12.4.20.

AN alloy of 3½ pts. of fine silver, 3½ pts. of standard silver, 1 pt. of 12-carat gold.—J. W. D.

Coating articles with metal. G. de Dudzele et Cie. E.P. 139,143, 5.8.19. Conv., 18.2.19.

THE articles (e.g. of iron or steel) are treated with a mercury salt solution, and a thin layer of a metal capable of forming an amalgam having great affinity for the coating metal is deposited by electrolytic means. This layer forms a complex amalgam with the iron and mercury, and the coating metal (e.g., lead, zinc, etc.) is applied by dipping. The electroplating may precede the treatment with a mercury salt.—J. W. D.

Electric arc welding and metal cutting; Electrodes for —. W. H. Boorne. E.P. 152,257, 3.2.20. Addn. to 132,354 (J., 1919, 827 A).

A COVERING for an electrode employed in electric welding in confined positions is composed of calcined magnesite, calcium carbonate, aluminium, graphite, and sodium silicate. Iron peroxide and/or ferrous silicate may be used instead of, or in addition to, the graphite.—J. S. G. T.

Electric welding, cutting, reducing, or like operations; Electrodes for —. C. J. Holslag. E.P. 152,733, 12.7.19.

THE electrode is provided at one or both ends with a coating or covering tapering away from the end.

Magnesium and chlorine; Apparatus and process for the electrolytic decomposition of anhydrous magnesium chloride and production of —. E. A. Ashcroft. E.P. 152,402, 9.7.19.

AN apparatus for the electrolytic production of magnesium from magnesium chloride consists of a pair of cast-steel cells arranged in series, in the lower part of which is a layer of molten lead alloyed with 5–10% of magnesium which is kept at constant level by a weir across the cell. The cells are connected by passages at the bottom with opposite pockets, which enable the alloy to be introduced or withdrawn as required. An electrolyte of fused anhydrous magnesium chloride (E.P. 152,401; p. 783 A) is superposed on the alloy, the cell walls in this part being lined with refractory material. Each cell is provided with a lid from which depend graphite anodes in one cell and iron or steel cathodes in the second one. In operation the magnesium produced in the primary cell is collected in the lead alloy, while in the second cell the metal withdrawn from the alloy floats on the electrolyte and is deposited on the iron or steel cathode from which it is removed periodically. The process is made continuous by ladling lead alloy from the primary into the secondary cell at suitable intervals and by the introduction into the primary cell of fresh magnesium chloride as required. The temperature of the cells should be maintained at 750° C. Quantitative yields of magnesium of a high degree of purity, and of chlorine, are obtained.—W. J. W.

Magnesium or alloys of magnesium; Production of — and a by-product [magnesium chloride]. E. A. Ashcroft. E.P. 152,403, 9.7.19.

HYDRATED magnesium chloride is dehydrated (E.P. 152,401; p. 783 A) and the anhydrous chloride electrolysed to produce magnesium or an alloy (E.P. 152,402; *supra*). The chlorine liberated is absorbed in magnesium oxide emulsion, thus producing magnesium chlorate as by-product and hydrated magnesium chloride, which after separation of the chlorate is utilised again in the process.—J. W. D.

Flux solder for aluminium; Combined —. A. J. Ansell. E.P. 152,486, 8.9.19.

TIN 6lb., zinc 2lb., aluminium 1½ lb., lead ¾ lb., and a hardener, consisting of 2 oz. of copper and 2 oz. of aluminium, are melted together with cryolite powder and lithium fluoride in a graphite crucible,

and the molten material is fluxed with manganese chloride and ammonium chloride.—J. W. D.

Magnetic separators for treating ferrous ores. F. Quinónero. E.P. 152,549, 24.12.19.

A ROTATING cylinder surrounding stationary magnets is mounted above a shaking table, and longitudinal projections (bars of copper) on the periphery of the cylinder engage with the ore particles on the table and facilitate separation of the non-magnetic from the magnetic particles, the latter being carried by the cylinder to a receptacle.

Ore-flotation agent; Process of producing an —. H. Cannon, C. Barbre, and E. H. Leslie, Assrs. to General Petroleum Corp. U.S.P. 1,337,542, 20.4.20. Appl., 8.10.17.

WATER which has been in contact with petroleum or petroleum products, especially with cracked oil during refining, is an efficient flotation agent. It is made alkaline and concentrated for transportation, and when required for use is treated with acid. It is used in conjunction with the oils commonly used for flotation.

Flotation process [for recovery of molybdenite]. E. B. Thornhill, Assr. to General Engineering Co. U.S.P. 1,338,264, 27.4.20. Appl., 8.3.18.

THE ore pulp is treated with oil as in the usual flotation process, whereby molybdenite is "coagulated" in preference to other minerals, e.g., iron and copper pyrites. The resulting concentrate is screened; the "uncoagulated" minerals pass through the screen and are returned for re-treatment.

Zinc and cadmium; Process for separating and recovering — by acid treatment. J. Leib. G.P. 322,142, 15.2.17.

PRODUCTS containing cadmium and zinc are stirred with water and sufficient concentrated acid is added to dissolve the zinc, leaving the other metals as a sponge or scum. The zinc solution is evaporated in a fireclay furnace the floor of which consists of a fireclay arch under which the heat is applied. The cadmium is recovered from the "sponge" by treating it with sulphuric acid and an oxidising agent, e.g., nitrous acid. From this solution the cadmium is precipitated by means of a zinc-iron couple.

—A. R. P.

Ore-roasting furnace; Annular, mechanical —. C. L. A. and H. G. H. Promnitz. G.P. 323,469, 18.3.13.

THE carrier for the stirrers is in the form of a closed ring and serves to close the inner side of the hearth. Each hearth has its own stirring mechanism, which is independent of that of the other hearths, so that it is possible to run each rabble backwards or forwards, fast or slow, or to stop it for cleaning or emptying one hearth without interfering with the operation of the others.—A. R. P.

Zirconium; Production of — from its ores or oxide. W. North and H. Loosli. G.P. 324,945, 15.11.19.

ZIRCONIUM ore or oxide is heated under pressure in an electric furnace in presence of a reducing agent such as charcoal. The formation of zirconium fume is thus avoided.—W. J. W.

Aluminium; Manufacture of —. V. Gerber. E.P. 139,194, 18.2.20. Conv., 18.2.19.

SEE U.S.P. 1,350,150 of 1920; J., 1920, 657 A.

XI.—ELECTRO-CHEMISTRY.

Galvanic cells and accumulators; New —. Pradel. Elektrotechn. Anzeiger, 1920, 70, 72. Chem.-Zeit., 1920, 44, Rep., 260.

A dry cell, of which the positive system may be renewed, is constituted of the combination lead peroxide, dilute sulphuric acid, zinc. The average discharge E.M.F. is 2.3 volts. When the cell runs down the zinc plates are replaced by others, and are meanwhile recharged between two lead electrodes in dilute sulphuric acid. Spent manganese dioxide employed as depolariser is revived by powdering, treating successively with solutions of salts which dissolve out salts of ammonium and zinc, with superheated steam under high pressure, and with ozone, hypochlorous acid, or a halogen. Alternatively, oxidation may be effected electrolytically, the electrolyte employed containing hypochlorous acid, chloric acid, a hypochlorite, or salts such as magnesium chloride, which yield a solution of a hypochlorite on being electrolysed, or potassium manganate or permanganate, bichromate, etc. —J. S. G. T.

XII.—FATS; OILS; WAXES.

Oils; Hydrogenation of —. M. Fréjacque. Chim. et Ind., 1920, 4, 443–456.

LINSEED oil with iodine value 160 was hydrogenated under the same conditions, with basic nickel carbonate, reduced respectively in dry hydrogen and in the oil itself, as catalyst, the amount of nickel in each case being 1% of the oil. With the nickel previously reduced at 160° C. the iodine value after 4 hrs. was 152, and with that reduced at 210° C. it was 133, whilst with the same catalyst reduced in the oil itself at 160° and 210° C. the iodine value of the oil was reduced to 70 and 20 respectively. These results confirm the conclusions of Siegmund and Suida (J., 1915, 970).—C. A. M.

Perilla oil. H. A. Gardner and P. C. Holdt. Paint Manufacturers' Assoc., U.S.A., Circ. 106, Oct., 1920. 8 pp.

PERILLA seed contains 33–35% of a greenish-yellow or brownish oil of characteristic, agreeable odour,

which in many respects resembles linseed oil. It dries to a tough film slightly more slowly than raw linseed oil, but the acceleration of oxygen absorption with the addition of a drier appears to be greater than is the case with linseed oil. Its most obvious defect is the tendency of the film to "crawl" or "creep" into droplets on a surface, a fault which can be inhibited by increasing its viscosity by bodying-up (blowing) or by admixture with an oil of lower surface tension, e.g., linseed or soya bean oil. A sample of perilla oil secured direct from the Orient had the following characters:—sp. gr. at 15.5° C., 0.9351; moisture and volatile matter, 0.07%; acid value, 7.0; iodine value, 198.8; saponif. value, 193.1; unsaponifiable matter, 1.07%; n_D^{25} = 1.4802. The wetting power of perilla oil is greater than that of linseed oil as measured by the determination of the oil absorption of pigments (J., 1920, 306 A), 20 g. of lithopone absorbing 4.7 c.c. and 5.2 c.c. of the two oils respectively. The oil shows no separation of mucilage on heating quickly to 310° C., and little darkening in colour takes place at this temperature, thus indicating its suitability for the manufacture of pale varnishes. As a paint vehicle perilla oil is equal to linseed oil in regard to weathering; the "creeping" effect observed when it is used in conjunction with white lead may be corrected by previously heating the oil to 500° F. (260° C.) or mixing it with a proportion of raw linseed oil.—A. de W.

Chia [Salvia hispanica] oil. H. A. Gardner and P. C. Holdt. Paint Manufacturers' Assoc., U.S.A., Circ. 105, Oct., 1920. 8 pp.

A SAMPLE of chia seeds from Mexico gave the following results:—Oil obtained by pressing, 22.33%; oil in press cake, 10.5%; nitrogen in cake, 3.6%; P_2O_5 in cake, 1.5%. The filtered oil gave the following data:—Sp. gr. at 15.5° C., 0.9338; acid value, 0.6; iodine value, 192.2; saponif. value, 192.2; unsaponifiable matter, 0.8%; n_D^{25} = 1.4855. The oil was clear and of light amber colour. It dried slowly in its raw state and the surface in a film tended to pull together at points, indicating high surface tension. When siccatised, the oil dried as rapidly as linseed oil. The "crawling" tendency of the oil film is practically overcome by heating to 500° F. (260° C.) for 15 mins., this treatment yielding an oil which when siccatised with a liquid drier, showed even superior drying power to linseed oil treated with the same amount of drier. The wetting power of the oil as measured by the method for determining the oil absorption of pigments (J., 1920, 306 A) was lower than that of linseed oil, 6.2 c.c. of chia oil as against 5.1 c.c. of linseed oil being absorbed by 20 g. of white lead. The maintenance of its colour during heat treatment indicates the suitability of chia oil for the manufacture of pale varnishes. It seems probable that several species of *Salvia* contain oils exhibiting varying degrees of drying power. —A. de W.

Fatty acids; Anhydrides of the higher aliphatic —. III. D. Holde and H. Smelkus. Ber., 1920, 53, 1889–1897.

THE dehydration of the fatty acids of linseed oil and of commercial olein by acetic anhydride at 150°–160° C. has been studied. Acetic acid and excess of acetic anhydride cannot be removed from the products by steam since the fatty anhydrides are thereby almost completely converted into the acids. Crystallisation from alcohol and distillation under diminished pressure are unsuitable for the separation of fatty anhydrides from the parent fatty acids, but this can be effected by means of solid sodium carbonate or aqueous solutions of the latter. The proportion of acid to anhydride in the mixtures cannot be determined by titration with N/10 or N/20 alcoholic alkali, which causes a gradual con-

version of the fatty acid into the corresponding ester and salt.—H. W.

Fatty acids; Anhydrides of the higher aliphatic —. IV. D. Holde and I. Tacke. Ber., 1920, 53, 1898—1907. (Cf. *supra*.)

THE mixed fatty acids from linseed and rapeseed oils and oleic acid can be satisfactorily dehydrated at 150°—160° C. with 3.5 times the amount of acetic anhydride theoretically necessary, and it is possible that this proportion can be further greatly reduced and that the operation can be effected at the ordinary pressure. The excess of reagent is removed by distillation under diminished pressure and the products are further purified by agitation with powdered sodium carbonate or aqueous sodium carbonate solution (5%). Their purity is conveniently examined by determination of the mol. wt. in freezing benzene. The mixtures have generally a higher melting point than the acids from which they are derived and, at the ordinary temperature, are semi-solid and sometimes partly crystalline. In viscosity, volatility, and refractive index they closely resemble the corresponding glycerides. They are decomposed by *N*/10 or more dilute alcoholic alkali into almost exactly equivalent amounts of fatty salt and ester, but the so-called saponification value can be determined in the usual manner. Mixed anhydrides of the fatty acid and acetic acid are not present.—H. W.

α -Monoglycerides; New synthesis of —. E. Fischer, M. Bergmann, and H. Bärwind. Ber., 1920, 53, 1589—1605.

ACETONEGLYCEROL, $(\text{CH}_3)_2\text{C} < \begin{matrix} \text{O} \cdot \text{CH}_2 \\ \text{CH} \cdot \text{CH}_2\text{OH} \end{matrix}$, reacts readily with acyl chlorides in the presence of quinoline yielding substances from which the acetone residue is easily removed, generally by treatment with acid, yielding α -monoglycerides. The preparation of α -benzoyl-, α -*p*-nitrobenzoyl-, α -stearyl-, α -lauryl-, and α -palmityl-glycerol is described together with that of several mixed glycerides obtained by the further action of acid chlorides on these products. (Cf. J.C.S., Dec.) —H. W.

Acetoneglycerol [isopropylideneglycerol] and its applicability to the preparation of pure α -glycerides. A compound of phosphoric acid and glycol. E. Fischer and E. Pfähler. Ber., 1920, 53, 1606—1621.

ACETONEGLYCEROL is transformed by acetic anhydride and pyridine into acetylisopropylideneglycerol, b.p. 84° C. at 9 mm., 87° C. at 12 mm., which is converted by *N*/4 sulphuric acid into α -monoacetin, b.p. 103° C. at 0.4 mm. Even at the lowest possible pressure slight decomposition occurs during distillation and it is thus very probable that all the mono- and di-glycerides described previously in the literature and purified by distillation under diminished pressure are not homogeneous. Phosphoryl chloride converts acetoneglycerol into isopropylidene- β - γ -dihydroxypropyl phosphate which is transformed by sulphuric acid into α -glyceryl phosphate and di-isopropylideneglycerol monophosphate. Ethyleneglycol is converted by phosphoryl chloride and pyridine at -20° C. into β -chloroethyl phosphate, $\text{Cl} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{O} \cdot \text{PO}(\text{OH})_2$. The introduction of the dihydroxypropyl complex into other substances is most readily effected by means of acetoneglycerol- α -iodohydrin; the chlorine atom of the chlorohydrin is too firmly retained for this purpose. —H. W.

Glycerin; Manufacture of —. Verbeek. Seifens.-Zeit., 1920, 44, 47, 133, 190, 234. Chem.-Zeit., 1920, 44, Rep., 187.

THE apparatus of van Ruymbeke (E.P. 24,556 of 1893 and 12,367 of 1894; J., 1894, 1070, 1208) is

the most suitable for the distillation of impure crude glycerins, and apparatus with rectifying columns for saponification glycerins. In the former method a sweet water containing 5—15% of glycerol is left, whilst in the latter the sweet water is practically free from glycerol. In van Ruymbeke's process it is best to use steam at a pressure of at least 10—14 atm. so as to obtain a temperature of at least 175° C. Better rectification is effected by having the columnar vessel of the condenser in a slanting rather than in a horizontal position. In the subsequent concentration of the distillate in the receiver a temperature of 125° C. must not be exceeded, and the pressure of steam is therefore reduced to 2 atm.—C. A. M.

Tung or other vegetable oils; Nitration of —. G. H. Howso. E.P. 152,095, 4.7 and 16.8.19.

FATTY oils, fatty acids from these, or mixtures thereof, are nitrated at reduced, atmospheric, or increased pressures with strong or dilute nitric acid in the presence of inert solvents, e.g., petroleum spirit or the naphthene residue from the nitration of Borneo spirit. For example, tung oil is mixed with 50% by vol. of petroleum spirit, the mixture mechanically agitated in a closed jacketed pan, and 10—15% of commercially pure nitric acid slowly run into the mixture, which may be heated not above 40° C. The mixture is maintained at this temperature and agitation continued until only a faint trace of free nitric acid remains. The excess of acid may be removed either by addition of a further quantity of tung oil and solvent or by addition of a solvent capable of nitration, e.g., heavy solvent naphtha. The nitrated mixture may then be used as such in the manufacture of varnishes, paints, rubber substitutes, insulators, etc., or the volatile solvent may be recovered in a reduced pressure recovery plant.—A. de W.

Powdered metals and reduced metallic compounds [as catalysts]; Making —. Process of making catalytic material [for hydrogenating oils]. C. Ellis. U.S.P. (A) 1,329,322 and (B) 1,329,323, 27.1.20. Appl., (A) 1.8.19 and (B) 31.1.19.

(A) A CATALYTIC material containing nickel or other metal with atomic weight between about 58.7 and 63.6 is reduced in paraffin wax, at the cracking temperature of the latter. (B) Catalytic material containing nickel in combination with an acid of the nitrogen oxide group is heated in a reducing atmosphere, sintering being prevented by the introduction of a diluting agent during the early stages of heating.—C. A. M.

Wool fat; Process of saponifying —. I. Lifschütz. G.P. 324,667, 28.5.18.

WOOL fat is digested with aqueous alkali solution at a moderate temperature until the fatty acids liberated from a sample show an acid value corresponding to the saponification value of the original fat.—C. A. M.

Soap; Process for the manufacture of —. J. J. Morel. E.P. 131,881, 13.8.19. Conv., 28.8.18.

THE sodium carbonate used in the manufacture, e.g., of oleic acid soap, is replaced by the crude sodium sulphite obtained, e.g., on fusing benzene-

sulphonic acid with sodium hydroxide. The sulphur dioxide liberated is either collected, or is used for decomposing calcareous soaps.—L. A. C.

Catalyst [for hydrogenating oils]. H. K. Moore, Assr. to Brown Co. U.S.P. 1,326,767, 30.12.19. Appl., 4.4.16

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Antimony sulphides; Chemical examination of —. A. van Rossem and P. Dekker. *Indiarubber J.*, 1920, 60, 905—908.

ANTIMONY pentasulphide is decomposed by hot carbon bisulphide with liberation of sulphur; the determination of the free sulphur content by extraction in the customary manner is therefore inaccurate. Provided that little or no antimony trisulphide is present, the estimation of free sulphur can be effected by treating 1 g. with 25 c.c. of boiling concentrated hydrochloric acid for 10 mins., the sulphur in the insoluble portion being determined by drying, extracting with carbon bisulphide, and weighing; this weight includes both the free sulphur and the sulphur formed by the reaction

and a correction is made in the calculation of the amount of original free sulphur. Weber's method for estimating free sulphur by removing the antimony sulphide with aqueous ammonia is applicable only in the absence of trisulphide and with the use of ammonia of the lowest possible concentration. Calcium sulphate is estimated by extracting with hot water and precipitation as calcium oxalate. In isolating possible adulterants by treating with a solution of caustic alkali, prolonged heating is inadvisable on account of the tendency of part of the antimony to separate again from solution.

—D. F. T.

Carbon black; Channel process of making —. R. O. Neal. *Chem. and Met. Eng.*, 1920, 23, 729—731.

The channel process of making carbon black from natural gas is that most widely employed. The condensing buildings are made of sheet iron attached to a steel frame-work, and in the case of those containing two groups of channels are 18 to 20 ft. wide and 80 to 115 ft. long. The condensation channels are of mild steel, 7 to 8 in. wide, bolted together in lengths up to 100 ft., and are supported by trucks running on overhead rails. The condensed carbon is removed by means of scrapers preferably in direct contact with the channels, while the trestles or tables on which the channels rest are moving in one direction only. Most of the plants have eight rows of such channels upon each table or trestle, which is moved continually to and fro over a distance of 55—60 ins. in 15 mins., and as a rule, there are side scrapers for removing the carbon from the sides of the channel beams. The carbon falls into hoppers and is then conveyed by screw conveyors to the bolting machine. The burners for the gas, between the hoppers, are fitted with lava tips made from steatite, which is subsequently hardened at 2000° F. (1090° C.). They should produce a uniform flame with uniform gas consumption. The size of the steel screen in the bolting machines usually ranges from 45 to 60 meshes per in.—C. A. M.

Carbon black; The disc, plate, and cylinder processes for the production of —. R. O. Neal. *Chem. and Met. Eng.*, 1920, 23, 785—789.

A DETAILED description of the plant used in each process is given, together with instructions for the care of the large number of gears that are required.

The disc and plate processes, in which the black is deposited on rotating discs of 36—42 in. diam., or on stationary or rotating plates of 24 ft. diam., produce approximately the same amount of black per 1000 cu. ft. of gas, but the cylinder system, in which the black is deposited on rotating cylinders, 3—8 ft. long and 8½ in. diam., produces much less, although the product is much more valuable, especially for making high-grade printing inks. Carbon black produced by cracking natural gas is very dense and of a grey colour and contains gritty particles which render it practically useless for most commercial purposes.—A. R. P.

Rosin tung esters ("tunga resin"); Production of — and application in varnish manufacture. H. A. Gardner and R. E. Coleman. *Paint Manufacturers' Assoc.*, U.S.A., Circ. 101, Aug., 1920. 22 pp.

NEUTRAL glycerin-rosin esters for use in varnish manufacture can be prepared in an open varnish pot by employing tung oil as an esterifying catalyst, whereby "tunga resin," an ester-like resin of low acid value is obtained. Rosin lost 19—21% of its weight as fume when heated alone to a temperature and for a time sufficient to carry out esterification with glycerin, whilst the acid value of the residue remained substantially unchanged. The presence of 6% of lime reduced the loss to 7%, and the acid value of the residue dropped from 158.5 to 78.5. On heating such limed rosin with 12% of its weight of glycerin to 350° F. (177° C.) in 20 mins., then to 440° F. (223° C.) in 20 mins., and finally to 500° F. (260° C.) in 10 mins. the acid value fell to 61, and the cloudiness due to the limed rosin disappeared. Under nearly similar conditions of experiment rosin and glycerin combined to only a small extent, a residue with an acid value of 141.6 being obtained, whilst the additional presence of 5% of tung oil resulted in a product with an acid value of 123.4. A brown tunga-resin of acid value (in alcohol) 21.8 (in alcohol-benzol 24.4) was obtained by the following method, the loss by fuming being 8.3%. 80 parts of tung oil is heated in 10 mins. to 350° F. (177° C.), 12 pts. of lime is added, and the temperature maintained for 20 mins. 200 pts. of rosin is then added and the temperature raised in 20 mins. to 425° F. (219° C.), the flocculent calcium tungate formed going into solution. The temperature is allowed to drop to 350° F. (177° C.), 30 pts. of glycerin added, the temperature raised in 20 mins. to 450° F. (232° C.), and then in 7 mins. to 500° F. (260° C.). The mass is then cooled to 475° F. (246° C.), and maintained thereat for 45 mins. The reduced losses by fuming during esterification in the presence of tung oil may be due to the head of froth formed by the tung oil acting as a protecting layer against oxidation by air. The methods of preparation of three typical varnishes comprising tunga-resin and tung oil are given (*cf.* J., 1920, 664A).

A. de W.

Varnish fume recovery. C. H. Jones. *Chem. and Met. Eng.*, 1920, 23, 16, 771—776.

THE necessity of reducing the nuisance caused by the escape of noxious fumes from the factory has led to the recovery of products previously regarded as waste and has thus resulted in considerably more economical working. Typical modern installations are described and illustrated with photographs and plans. The fires are operated with positive suction to ensure a good draught and minimise smoke issuing from a short pipe on the roof of the pent-house which serves in place of a stack. The charged gum pot is placed on the fire and a fume exhaust cover, attached to a collapsible swinging pipe easily manipulated by hand, lowered on to it. "Cooking" for 1½ hrs. was necessary under the old system, but 30 mins. is sufficient with the new arrangement. The lid and exhaust system minimise the possibility

of flashing or burning, and the insertion of screens in the flues permits of the location of spontaneous combustion. After incorporation of the oil the gum pots with their charges are removed to the cooling room and again connected with another portion of the same fume recovery system. The fumes from these two sources are drawn through a water-scrubbing tank in a pent-house on the upper floor, where the heavier particles settle out and the remainder pass through a turbine to a similar tank filled with lime water. Products are recovered from the condensed matter on the inner surfaces of the piping ahead of the water-tank and from the deposit in the water-scrubbing tank, and the lime-soap emulsion formed in the lime scrubber is boiled to remove excess of lime water and neutralised with acid. The recovered products are ultimately returned to the gum pot. The ultimate exhaust from the fume recovery system possesses only a faint soapy odour. The thinner recovery system operates entirely separately from the fume recovery system. The condensing system returns the condensed solvent to the gum pot, a loss of only 2% of the total solvents used being thus obtained. The finished varnish is pumped to large settling tanks and thence through a De Laval centrifugal separator, such clarification having been found superior to methods involving filtration. Records of runs of typical varnishes in a non-recovery plant are given and show the losses in gum-resin as fume to be 30–42%.—A. de W.

Japan lac; Main constituent of —. VII. *Urushiol monomethyl ether and the mechanism of the oxidation of urushiol.* R. Majima and G. Takayama. Ber., 1920, 53, 1907–1916. (Cf. J., 1916, 128, 129, 1007.)

ONE of the two hydroxy groups of urushiol is more readily methylated than the other and the product obtained by partial methylation is shown by a comparison of the properties of its tetrahydro-derivative with those of 2-hydroxy-*m*-tolyl methyl ether to be 2-hydroxy-3-methoxyurushiol. The tolyl derivative can be oxidised to a derivative of diphenquinone and since precisely similar phenomena are observed during the oxidation of hydro-urushiol it appears valid to conclude that analogously constituted products are also formed in this case. (Cf. J.C.S., Dec.)—H. W.

Resin acids; Relationship of retene to —. *Hydrogenated retenes.* A. J. Virtanen. Ber., 1920, 53, 1880–1889.

RETENE is converted by sodium and boiling amyl alcohol into dihydroretene, m.p. 98.5°C., b.p. 208°–210°C. at 10 mm., and tetrahydroretene, yellowish oil, b.p. 180°–183°C. at 10 mm., sp. gr. 1.0057 at 10°/4°C., $n_D^{20}=1.56061$. Fuming hydriodic acid (sp. gr. 1.96) and red phosphorus transform retene into hexahydroretene, b.p. 175°–177°C. at 10 mm., sp. gr. 0.9802 at 20°/4°C., $n_D^{20}=1.54705$, octahydroretene, b.p. 163°–165°C. at 10 mm., sp. gr. 0.9578 at 20°/4°C., $n_D^{20}=1.53023$, dekahydroretene, b.p. 155°–158°C. at 10 mm., sp. gr. 0.9342 at 20°/4°C., $n_D^{20}=1.51501$, and dodekahydroretene, b.p. 148°–150°C. at 10 mm., sp. gr. 0.8985 at 20°/4°C., $n_D^{20}=1.48510$. The author expresses the view that all resin acids having the formula $C_{20}H_{30}O_2$ contain in their molecule a hydrogenised retene nucleus. (Cf. J.C.S., Dec.)—H. W.

Tannins. VI. Chebulinic acid. II. K. Freudenberg and B. Fick. Ber., 1920, 53, 1728–1736. (Cf. J., 1919, 591 A.)

THE crystalline product obtained by the action of hot water on chebulinic acid is definitely proved to be a digalloylglucose; since it is unaffected by emulsin, phaeolunatae, or yeast extract it is not a β -glucose. The amorphous acid produced simultaneously yields a sparingly soluble brucine salt and appears to have the formula, $C_{14}H_{14}O_{11}$; it gives pyrogallol when distilled under diminished pressure. (Cf. J.C.S., Dec.)—H. W.

Gelatin; Swelling of — in acids. W. R. Atkin. J. Soc. Leather Trades' Chem., 1920, 4, 248–257.

THE results obtained by different workers at different times in swelling experiments on gelatin left for 48 hrs. in solutions of various monobasic acids of varying concentrations are compared, and it is shown by curves that the maximum swelling occurs at a definite hydron concentration, $p_H=2.4$ or $0.004N$. The curves indicate that acetic acid might also show a maximum swelling if solution of the gelatin did not take place at that concentration. The quantity, e (Pröcter and Wilson, J., 1916, 645), representing the excess of the concentration of diffusible ions in the jelly over that of the external solution, exhibits a maximum value at the point of maximum swelling. Minimum swelling is obtained at the isoelectric point of gelatin, $p_H=4.6$. Thus the quantity, e , and the swelling are functions of the hydron concentration of the external acid solution.—D. W.

PATENTS.

Tannin; Manufacture of —. Chem. Fabr. Grünau, Landshoff and Meyer, A.-G., and L. Schlein. G.P. 323,135, 25.1.16.

SUBSTANCES containing tannin are extracted with water, the extract is kept below 11° C. for a prolonged period, and the non-tannins which separate are filtered off.—W. J. W.

Leather for linings, especially from inferior portions of hides; Process for increasing the durability of —. H. Hoffmeister and J. Paessler. G.P. 324,495, 16.3.17.

LEATHER, after tanning, is steeped in a solution of wood-tar in benzene or methyl alcohol, in presence of an organic acid, then dried, and dressed. If a vegetable tanning agent has been used, the excess is first washed out with water containing formalin, and the leather is dried before steeping in the wood-tar solution. In the case of tawed leather, the treatment with wood-tar is preceded by immersing the leather in a strong solution of a tanning agent or in purified, concentrated cellulose waste-liquor, followed by drying.—W. J. W.

XVI.—SOILS; FERTILISERS.

Soils; Flocculation of —. N. M. Comber. J. Agric. Sci., 1920, 10, 425—436.

THE silt fraction of soils, when suspended in water, is most easily flocculated by calcium salts when the suspension is neutral, the addition of alkali stabilising the suspension. The clay fraction, however, is flocculated from alkaline suspensions more readily than from neutral suspensions. It is suggested that the clay particles are protected by emulsoid colloids, and thus behave as emulsoids and not suspensoids. In this way the action of lime which, although alkaline, flocculates clay is correlated with the present views on colloid chemistry. The experimental results indicate that the clay, as an emulsoid, protects the larger particles in a soil which by themselves are suspensoid. Fine silt soils are not flocculated by calcium hydroxide owing to the inefficiency of the relatively small amount of emulsoid clay in protecting the larger suspensoid surface exposed by the fine silt.—W. G.

Soils; Qualitative test for sour —. N. M. Comber. J. Agric. Sci., 1920, 10, 420—424.

ABOUT 2—3 g. of the air-dried soil is shaken in a test-tube with 5 c.c. of a 1° alcoholic solution of potassium thiocyanate. The development of a pink or red coloration in the liquid on standing indicates that the soil has a lime requirement as measured by the Hutchinson-MacLennan method (J., 1914, 932). The test is based on interchange between the potassium ions in the thiocyanate solution and the iron and aluminium ions in the sour soil, and cannot be used for quantitative measurements, but on the same soil the test may afford useful indications of the variation in acidity.—W. G.

Soil; Determination of nitrates in —. A. L. Whiting, T. E. Richmond, and W. R. Schoonover. J. Ind. Eng. Chem., 1920, 12, 982—984.

ONE hundred g. of the soil is shaken for 3 hrs. with 300 c.c. of 0.5% hydrochloric acid, the mixture allowed to settle for 18 hrs., and 200 c.c. of the clear liquid then transferred to a flask containing 5 g. of sodium hydroxide. The contents of the flask are boiled until the volume is reduced to about 25 c.c. (if urea is present, the evaporation is continued to dryness), 200 c.c. of water is added together with 0.5 g. of Devarda's alloy (Al 50, Cu 45, Zn 5%) and the mixture is distilled for 40 mins., the ammonia being collected in standardised acid.

—W. P. S.

Aluminium as a factor in soil acidity. J. J. Mirasol. Soil Sci., 1920, 10, 153—217.

FURTHER evidence is adduced in support of the view that aluminium is apparently the determining factor in the acidity of many soils (cf. Hartwell and Pember, J., 1919, 112a). The toxic effect due to aluminium may be corrected by the application of calcium carbonate, and may be reduced by the application of calcium superphosphate. In so far as aluminium is a factor in soil acidity, the author considers that Hopkins' method (cf. U.S. Dept. Agric. Bur. Chem. Bull., 1903, 73, 114) is the best one for soil acidity determinations. (Cf. J.C.S., Dec.)—W. G.

Nitrogen economy in the soil as influenced by various crops grown under control conditions. R. C. Wright. Soil Sci., 1920, 10, 249—289.

IN pot culture experiments it was found that frequent cultivation and consequent excessive aeration caused a loss of total nitrogen. Under certain crops there was a loss of nitrogen in excess of that recovered in the crops, the actual loss varying with the crop and the soil on which it was grown. This loss was found with certain leguminous as well as non-leguminous crops. Under the experimental conditions, where there was nitrogen-fixation by the growth of certain legumes, this nitrogen was found in the crop above the ground, and if the crop was removed and not dug in, the soil was depleted of nitrogen in the same way as if a non-leguminous crop had been grown and removed. The losses of nitrogen are to be attributed to volatilisation of either free nitrogen or ammonia.—W. G.

Phosphate rock and sulphur; Co-operative experiments for the composting of —. W. B. Ellett and W. G. Harris. Soil Sci., 1920, 10, 315—325.

UNDER the experimental conditions the addition of sulphur to a compost of soil and rock phosphate increased the availability of the phosphate, and a slightly better result still was obtained if, in addition, horse manure was added. In the absence of sulphur the manure was not effective. Oxidation of the sulphur preceded the increase in availability of the phosphate. The addition of rock phosphate to manure (a mixture of horse manure and cut straw) checked fermentation slightly and reduced the loss of dry matter and nitrogen. A still further reduction was effected when sulphur also was added. In this case addition of phosphate favoured nitrate formation, whilst addition of sulphur favoured ammonification. A large number of Virginia soils were examined and showed very great variation in their powers of oxidising sulphur.—W. G.

Sulphur; Influence of initial reaction on the oxidation of — and the formation of available phosphates. J. G. Lipman and J. S. Joffe. Soil Sci., 1920, 10, 327—332.

THE results given show no advantage in starting with a relatively high hydrogen-ion concentration in the soil, produced by the addition of sulphuric acid, for the conversion of rock phosphate into a soluble form (cf. J., 1920, 166a).—W. G.

Phosphates in basic slag; Solubility in citric acid of —. A. Kaysser. Chem.-Zeit., 1920, 44, 826.

IN molten slag the phosphate exists in the form of tricalcium phosphate having a high solubility in citric acid. If the slag is slowly cooled, brown crystals are formed which are only slightly soluble; these consist of tetracalcium phosphate produced by interaction of tribasic phosphate with lime separated from its combination with silicic acid in presence of iron and manganese. Rapid cooling prevents this conversion of the soluble into the insoluble compound. Addition of silica to the slag increases the solubility of the phosphate owing to

its combination with free lime, and possibly in part to a mechanical cooling effect. On the other hand, fluorspar increases the amount of lime and causes loss of silica, the result being to diminish the solubility of the phosphate.—W. J. W.

Crude calcium cyanamide; Determination of cyanamide-nitrogen in —. H. Neubauer. *Z. angew. Chem.*, 1920, 33, 247–248, 254–256.

ESTIMATIONS of the total nitrogen in crude cyanamide do not indicate the condition of the material, as they do not discriminate between nitrogen present as cyanamide and as dicyanodiamide, which latter compound is formed in deteriorated cyanamide and is injurious. In the method of treating an aqueous cyanamide solution with nascent hydrogen, the most accurate results are obtained when a weak acid is used, and at the same time an active evolution of hydrogen is secured, and for this reason acetic acid has been employed with Arnd's alloy (Cu 60%, Mg 40%). The crude cyanamide should first be treated with pure acetone to dissolve any dicyanodiamide present. 1 g. of finely powdered material is placed on a cotton wool filter, and 100 c.c. of acetone in successive amounts of 20 c.c. is poured on it. The residue is transferred to a distillation flask, and 3 g. of Arnd's alloy, 5 c.c. of 20% magnesium chloride solution, and 15 c.c. of glacial acetic acid are added, the mixture being shaken, and loss by spitting guarded against. After 10 mins. a further 3 g. of alloy is added, the sides of the flask are rinsed and the contents allowed to stand for 10 mins., after which they are diluted to 300 c.c., some paraffin is added to reduce frothing, and after addition of alkali, the ammonia is distilled off and estimated; the nitrogen present as cyanamide can then be calculated. To ascertain the degree of deterioration of the original material, the acetone filtrate may be collected in a flask containing oxalic acid to fix any ammonia present, the acetone distilled off on a water-bath, and the nitrogen estimated by the Kjeldahl method. Small amounts of nitrogen retained by the carbon in the crude cyanamide are determined by acidifying the residue from the ammonia distillation, adding water, and shaking the mixture, after which the separated residue is treated by the Kjeldahl process.—W. J. W.

Phosphates; Mechanical treatment of tricalcic —. W. P. Thompson. From La Comp. des Phosphates de Constantine. E.P. 151,684, 1.4.6.19.

NATURAL phosphates consisting of material rich in phosphate associated with poor material are treated by grinding sufficiently to reduce the rich material to a granular condition, the poor material coating the richer as a powder. The material is passed through a rotary disintegrator, which picks the material up and causes it to fall on to beater arms. In this way the granules are separated from the powder and the whole is held in suspension in the air. A strong current is blown through the disintegrator and the material is carried into a series of compartments in which the particles are separated according to density. The granules fall first, forming a fraction richer in phosphate than the original. The powder forms a second fraction, and is sufficiently fine to dissolve completely in citric acid solution.—J. H. J.

Trees and other growing plants with wood-like stems; Treatment of growing —. A. A. Lockwood. E.P. 152,269, 15.3.20.

To stimulate the growth of trees, or to free them

from parasites, or to improve their fruit, a hole is bored in the lower part of the stem, or in the root, and suitable liquids or solutions are poured or siphoned in, the treatment commencing after the sap has begun to flow. Ammonium or sodium nitrate is beneficial to growth, solutions of citric or malic acid and iron citrate improve the quality and colour of pears and apples, while for the destruction of parasites, solutions containing both nitrogen and sulphur, such as ammonium sulphate, or mixtures of sodium sulphide and an alkali nitrate, have proved effective. Examples are given of the use of 5% sodium nitrate solution and 10% ammonium sulphate solution.—W. J. W.

Soil and seed inoculation. C. F. Diller. U.S.P. 1,354,808, 5.10.20. Appl., 29.10.19.

SELECTED soil organisms are freed from organic nutrient material and grown in water containing a small amount of an inorganic stimulating salt.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Cane juice; Influence of the amino-acids in — on sugar technology. H. I. Waterman and J. W. L. van Ligten. *Chem. Weekblad*, 1920, 17, 559–562.

THE previous observation of Waterman (J., 1918, 133A), that amino-acids inhibit the breaking down of the monoses by sodium hydroxide, is found to hold also for calcium hydroxide. Dextrose solutions were heated to various temperatures in presence of various quantities of lime, both with and without addition of amino-acids, and the quantity of sugar left in each case determined by the polarimeter. In the control tests the sugar was rapidly destroyed, and the solutions darkened, but amino-acids were found in nearly all cases to exert important inhibitory effects. The observations are of importance for the sugar industry, since the amino-acids present in the expressed juices must to some extent prevent destruction of the monoses by the lime used; the lime solutions used are controlled by titration with acids in presence of phenolphthalein; the amino-acids do not markedly affect this indicator.—S. I. L.

Beet-sugar factory products; Determination of moisture in —. V. L. Aikin. *J. Ind. Eng. Chem.*, 1920, 12, 979–981.

ABOUT 25 g. of sand (digested previously with hot hydrochloric acid, washed, dried, and passed through a 0.25 mm.-mesh sieve) is placed in a basin, dried, and weighed; a quantity of the sample, e.g., molasses, massecuites, etc., containing not more than 1 g. of dry substance, is then weighed into the basin, 1 c.c. of water is added, the basin is placed on a water-bath, and the mixture stirred for 3 mins. and dried at 105° C. for 6 hrs., or until the loss in weight after 1 hr. drying is less than 0.1%. —W. P. S.

Sucrose; Mechanism of the inversion of —. *Studies in catalysis.* XII. C. M. Jones and W. C. McC. Lewis. *Chem. Soc. Trans.*, 1920, 117, 1120–1133.

THE velocity of the inversion of sucrose in presence of N/10 sulphuric acid was determined at 20°, 30°, 40°, and 50° C., at various concentrations of sucrose from 10 g. to 70 g. per 100 c.c. of solution. With increasing concentration a definite increase in the velocity constant was observed. The average activities of the hydrogen ion were determined electrometrically in the various solutions, and it is shown that the alteration in the velocity constant can be completely accounted for by allowing for the stoichiometric correction for the water present

and for the change in the activity of the hydrogen ions. The inversion process is bimolecular, consisting first of the union of the non-hydrated hydrogen ion with a non-hydrated sucrose molecule, this process being practically instantaneous, and secondly the actual inversion reaction. The activity of the hydrogen ion is found to be an exponential function of the concentration of sucrose and water present, and the environmental catalytic influence of a molecule of sucrose is identical in magnitude with that exerted by a molecule of dextrose plus a molecule of levulose.—G. F. M.

Polysaccharides. I. Methylation of starch. P. Karrer. *Helv. Chim. Acta*, 1920, 3, 620—625.

THREE products obtained by methylating starch contained respectively 1, about 1.5, and 2 methoxy groups per $C_6H_{10}O_5$; they did not reduce Fehling's solution and yielded respectively reddish-violet, brownish-yellow, and almost imperceptibly yellow colorations with iodine. Preliminary molecular weight determinations on the third preparation indicated the value 1000—2000. (Cf. J.C.S., Dec.) —T. H. P.

XVIII.—FERMENTATION INDUSTRIES.

Diastatic preparations; Technical method for the determination of the saccharogenic power of —. K. Oshima. *J. Ind. Eng. Chem.*, 1920, 12, 991—993.

TEN c.c. of a solution of the sample is added to 100 c.c. of 2% soluble starch solution heated previously to 40° C.; the mixture is kept at this temperature for 30 mins., and 10 c.c. of N/5 sodium hydroxide solution is then added. Graduated quantities of this mixture are added to a series of test-tubes each containing 5 c.c. of Fehling's solution, the tubes are heated in a boiling water-bath for 10 mins., and the smallest quantity of the mixture required to reduce the Fehling's solution is noted. Formulæ and tables are given for calculating the results obtained into Lintner values.

—W. P. S.

Saccharase (invertase) preparations; Preparation of highly active —. H. von Euler and O. Svanberg. *Z. physiol. Chem.*, 1919, 167, 269—314.

VARIOUS highly active preparations of invertase were obtained from autolysed yeast by means of precipitation with alcohol. By quantitative estimations of the activity of the different preparations it was found that about two-thirds of the total invertase of the autolysed yeast remains in the pasty part after the juice has been filtered off. The authors calculate from the relative activities of one of their purest preparations and of dried yeast that their preparation of invertase forms about 1/100 part by weight of the total dry matter of the cell. Allowing for the moisture of the fresh yeast cell and for the invertase retained by the pasty portion of the

autolysed yeast, the active preparation would therefore form 1/900 part of the fresh yeast from which it was prepared. The authors at the same time admit that their best preparation is by no means pure.—S. S. Z.

Invertase action; Theory of —. I. Michaelis and M. Rothstein. *Biochem. Zeits.*, 1920, 110, 217—231.

INVERTASE combines with 1 mol. of sucrose and forms acid having a dissociation constant 3×10^{-7} . This acid dissociates in solution. The undissociated molecules of the acid decompose spontaneously into the products of the enzymic degradation. The anions, on the other hand, are stable. This theory explains the influence of the reaction on the action of the enzyme within certain limits of hydrogen ion concentration.—S. S. Z.

Enzymes; Influence of temperature on — especially on rennet and pepsin. A. König. *Biochem. Zeits.*, 1920, 110, 266—287.

RENNET and thrombin are more stable against high temperatures in concentrated solutions and in glycerol than in dilute solutions. The inactivation of rennet by heat may be delayed by increasing the quantity of milk, as the latter contains protective substances. Increase in temperature up to a certain limit accelerates the action of rennet. The inactivating influence becomes evident only at 45° C. The inactivation of pepsin and diastase also only becomes apparent at 45° C. No difference as regards inactivation by heat is observed in concentrated and in dilute solutions of pepsin. The different behaviour of pepsin and rennet as regards inactivation by heat supports the theory that they are different enzymes.—S. S. Z.

Yeast nutrition and fermentation. Does development of yeast occur without fermentation of sugar? T. Bokorny. *Centr. Bakt.*, 1920, 11, 50, 23—33.

THE author finds that it is possible for considerable increase of yeast to occur in solutions containing no trace of sugar. Besides the ordinary fermentable sugars, rhamnose, arabinose, lactose, peptone, asparagine and other amides, tartaric, acetic, and citric acids and, under certain conditions, glycerol are all capable of supplying yeast with the carbon necessary for its growth. (Cf. J.C.S., Dec.) —T. H. P.

Alcoholic fermentation. Effect of pyruvates, aldehydes and Methylene Blue on fermentation of glucose [dextrose] by yeast juice and zym in presence of phosphate. A. Harden and F. R. Henley. *Biochem. J.*, 1920, 14, 642—653.

EXPERIMENTAL evidence is brought forward to show that aldehydes and pyruvates act as hydrogen acceptors. According to the pyruvic acid theory, the final stage of the alcoholic fermentation of sugar is the reduction of acetaldehyde (produced by decompositions of pyruvic acid), a reaction which proceeds so rapidly that only an extremely small concentration of aldehyde is present during normal fermentation. Further, the production of the pyruvic acid from sugar appears only to be possible when some acceptor for hydrogen is present. Some such acceptor is probably more or less rapidly formed and reduced during the period of delay which follows on the addition of phosphate, this process being accompanied by a corresponding increase in the formation of pyruvic acid, until sufficient of this is being produced to provide the amount of acetaldehyde necessary for the maximum effect. When, however, easily reducible aldehydes or Methylene Blue are added, these act as acceptors and a much more rapid attainment of the maximum becomes possible.—J. C. D.

Typhus-paratyphus group; Decomposition of pentoses by bacteria of the ——. W. Stern. Centr. Bakt., 1918, I., 82, 49—56.

Typhus bacilli decompose xylose, but not arabinose. Paratyphus A bacilli decompose arabinose with liberation of gas, but they do not attack xylose; paratyphus B bacilli, however, decompose both arabinose and xylose, a reducing action and formation of gas taking place in most cases. This behaviour towards pentoses is absolutely characteristic and furnishes a valuable means of differentiating typhus and paratyphus bacteria.

—T. H. P.

Alcohol; Detection of denatured — in spirits. P. Hasse. Pharm. Zentralh., 1920, 61, 613—616.

THE method depends on the detection of acetone and pyridine which are contained in German denatured alcohol. Ten c.c. of the spirit (e.g., brandy) containing not more than 50% of alcohol is acidified with sulphuric acid and 5 c.c. is distilled; 0.5 c.c. of the distillate is then treated with 1 c.c. of ammonium sulphate solution (ammonium sulphate, 30 g., water 45, and concentrated ammonia, 10 c.c.) and 2 drops of sodium nitroprusside solution (sodium nitroprusside, 1 g., water, 4 c.c.). A violet-red coloration develops within 30 mins. if as little as 0.01% of acetone is present. To detect pyridine, the distillation residue is rendered slightly alkaline and its odour observed. The alkaline mixture is then distilled, and 1 c.c. of distillate collected and treated with 0.3 c.c. of 2% mercuric chloride solution. A white crystalline precipitate forms gradually according to the amount of pyridine present. On applying the test to brandy to which denatured alcohol containing 0.5% of pyridine (4 drops to 100 c.c. of brandy) had been added the precipitate appeared after about 20 hrs.; with larger quantities of the denatured alcohol the precipitate appears much sooner.—W. P. S.

Inversion of sucrose. Jones and Lewis. See XVII.

Yeast fermentation. Masters and Maughan. See XIXA.

PATENTS.

Malt; Method and apparatus for grinding —. H. Schott. E.P. 147,072, 6.7.20. Conv., 25.6.19.

A THREE-passage mill with only three rollers is claimed. The malt is crushed between the first and second rollers, separated into groats and spelt by sifting, and these are ground separately but simultaneously between the second and third rollers. The groats between the middle portions and the spelt between the two end portions of the rollers.

Yeast; Manufacture of — using waste beetroot pressings and other expressed saccharine liquids. O. Reinke. G.P. 324,865, 1.11.18.

THE saccharine liquid used for cultivation of the yeast is enriched, after pitching, with inorganic nutrient constituents by the addition of sludge from the refining of sugar, or a solution obtained by treating such sludge with hydrochloric acid until an acid phosphate reaction is obtained.—C. A. M.

XIXA.—FOODS.

Flours; Action of hydrogen peroxide on —. Marion. Comptes rend., 1920, 171, 804—806.

ALL flours contain a catalase, in amount varying with the percentage extraction, the offals having the highest content. By measuring the volume of oxygen liberated in a given time from a given

amount of hydrogen peroxide by a given weight of flour, an idea of the amount of extraction of the flour can be obtained. The method is more accurate and more rapid than the ordinary chemical methods.—W. G.

Bread-making properties of flour; Effect of certain organic substances on the — and on the fermentation of yeast. H. Masters and M. Maughan. Biochem. J., 1920, 14, 586—602.

THE amount of fermentation produced by yeast with sugar and water and in the dough varied with the age of the yeast. The maximum effect was obtained on the second or third day after the yeast had been compressed. The ratio of fermentation of the yeast with sugar and water to the fermentation in the dough was approximately constant. The maximum increase in volume on baking was obtained, under the conditions of the experiments, when the dough was allowed to rise for 40 mins., but this factor may vary with the proportion of the different ingredients used. The acidity of the dough increased with the time of fermentation, and the acidity of the bread decreased with the moisture content. The addition of lime-water to bread does not appear to prevent the production of acid, but it neutralises any acid formed; in the presence of lime-water a smaller loaf was obtained. On the addition of fresh ox-serum the maximum increase in the size of the loaf was produced with 1 pt. of serum to 100 pts. of flour. The power of the serum to increase the size of the loaf diminished rapidly on keeping, but was not destroyed by heating to 50°—60° C. With phosphates the best results were obtained when monosodium dihydrogen phosphate was added in the proportion of 1 pt. of phosphate to 200 pts. of flour. Neither phosphate nor serum produced any increase in the size of the loaf when the bread was raised with a chemical raising agent. Raw potato, cooked potato, and potato flour, when substituted for an equivalent amount of wheat flour, diminished the expansion of the dough on fermentation, but both raw and cooked potato gave a larger loaf, the increase being greater with cooked than with raw potato.—J. C. D.

Milk; Limitations of the reductase test for determining the quality of —. O. Rahn. Milchw. Zentr., 1920, 49, 287—290.

WHILST the Methylene Blue reduction test has a certain value and is better than no test at all, the results obtained by it show many abnormalities, and the information yielded by the test is in no way as reliable as that given by a chemical and bacteriological examination.—W. P. S.

Tripeptide from casein which contains tryptophan. S. Fränkel and E. Nassau. Biochem. Zeits., 1920, 110, 287—299.

A TRIPEPTIDE containing 2 mols. of tryptophan and 1 mol. of alanine was obtained from the products of hydrolysis of casein with potassium hydroxide. (Cf. J.C.S., Dec.)—S. S. Z.

Proteins; Free amino groups of the —. I. S. Edlbacher. Z. physiol. Chem., 1919, 107, 52—73.

THE N-methyl values of proteins of different origin and composition such as gelatin, casein, globin, Bence-Jones protein, edestin, and pumpkin globulin are of the same order. Clupeine sulphate and sturine sulphate also show similar N-methyl values, while esocin sulphate and scombrin sulphate are not methylated at all. Gelatin hydrolysed with alkali for $\frac{1}{2}$ hr. gives a higher N-methyl value than unhydrolysed gelatin. On hydrolysing gelatin with acid the ratio N-methyl value/"formol" value falls after the first $\frac{1}{2}$ hr. of hydrolysis to about a half of the original value, but subsequently remains constant. The same fall in the ratio of the two

values is observed when gelatin and casein and clupeme sulphate are hydrolysed by tryptic digestion.—S. S. Z.

Proteins; Ion series and the physical properties of —. J. Loeb. *J. Gen. Physiol.*, 1920, 3, 85—106.

THE author deals fully with the influence of acids and alkalis on the physical properties of proteins such as gelatin and egg albumin. (*Cf. J.C.S., Dec.*) —J. C. D.

Meats; Utilisation of kid, rabbit, horse and seal — as food. A. D. Holmes and H. J. Denel, jun. *J. Ind. Eng. Chem.*, 1920, 12, 975—977.

THE digestibility of the four meats mentioned was proved to be essentially the same as that of other and better-known meats.—W. P. S.

Oat grain and straw; Composition and properties of —. R. A. Berry. *J. Agric. Sci.*, 1920, 10, 359—414.

A VERY detailed study of the factors affecting the composition and properties of oat grain with a briefer study of the straw. The moisture content of the grain varies considerably with the locality in which it is grown, the length of time after threshing, and the hygrometric condition of the atmosphere. Most of the fatty substance in the grain is present in the aleurone layer, only about 11—12% being found in the germ. The ether extract always contains some finely divided solid matter in suspension, varying in amount from 0.25 to 6% of the total. Free fatty acids, whilst almost absent in the oil from freshly ground kernels, rapidly increase if the meal is kept. Drying the grain, as is done in the manufacture of oatmeal, diminishes the rate of hydrolysis of the fat. In the growing oat, under the soil and climatic conditions at Kilmarneck, the absorption of nitrogen and potassium from the soil is practically complete by the time the kernel begins to develop, whilst the absorption of phosphorus and total mineral matter and the accumulation of dry matter continues until the plant is mature. Migration of nitrogen, phosphorus, and potassium compounds from the straw, husk, and chaff into the kernel proceeds until maturity is reached. The component grains in a spikelet vary in weight, proportion of husk, and chemical composition; on an average the larger grains are richer in oil and nitrogen. The compositions of the kernel and of the grain of a large number of varieties of oats are tabulated. In a particular group in the scheme of tabulation a connexion is shown to exist between the weight of the kernel and other characters of the grain. Thus in the case of white grains with a thin husk, as the kernel increased in weight, the proportion of husk decreased, the oil and fibre diminished, while the carbohydrates, the yield of grain per acre and the proportion of grain to grain and straw increased. The "meal power" of oats calculated from the "kiln dried" grain varied in proportion to the amount of kernel in the grain. Oatmeal from Scotch oats contained a larger proportion of water, nitrogen, and ash than did an inferior sample from Plate oats. Yield of grain per acre is associated directly with the average size of individual grains. The larger grain gives the greater yield, weight per bushel and proportion of kernel. The production of straw varies in the opposite direction to that of the yield of grain. Seasonal changes and application of fertilisers produced comparatively little change in the composition of the grain. Seed sown in January yielded grain, on an average, heavier and containing less husk than later sown seed. Locality, including elevation, climatic, and soil conditions, was the cause of the greatest modification in the characters of the grain. Compared with home-grown oats,

imported oats arriving in Glasgow had a grain which was drier, smaller, contained a thicker husk, was richer in nitrogen and oil, and had a lower weight per bushel. The kernel contained more fibre. Of the imported oats, the grain from Manitoba was the larger and heavier per bushel. —W. G.

Moisture content of cereals; Automatic indicator of the —. M. Chopin. *Comptes rend.*, 1920, 171, 860—862.

AN automatic drying apparatus is figured and described. The grain is measured, not weighed, and its passage through a vertical electrically-heated tube of known capacity is controlled by valves. The moisture driven off is led to a condenser and is collected and measured. By means of suitable mechanical devices the process can be made continuous.—W. G.

Straw; Digestibility of — after treatment with soda. W. Godden. *J. Agric. Sci.*, 1920, 10, 437—456.

WHEN chopped oat straw is soaked overnight in a 1.5% solution of sodium hydroxide and then steamed the next morning for 1 hr. in a farm steamer, a product is obtained which is practically neutral and may be fed as such or after washing with water. By this treatment the digestibility (for sheep) of the organic matter of the straw is increased from 47.3% to 73.7%, of the nitrogen-free extractives from 39.6% to 62.9%, and of the crude fibre from 60.1% to 87.4%. For maintenance purposes, as estimated by the proportion usefully digested, the dry matter of the treated straw has roughly 1½ times the value of the original dry matter, whilst for production purposes, measured by the proportion available after digestion for producing growth, its value is nearly double. The loss of dry matter involved in the treatment amounts to 20%, or if the straw is washed after treatment to 33.5%. Allowing for this, there is still a clear gain in efficiency of about 20% for maintenance purposes and 45% for production purposes if the treated straw is fed without washing.—W. G.

Peat moss; Digestibility of — after treatment with acid. W. Godden. *J. Agric. Sci.*, 1920, 10, 457—459.

A PROPRIETARY article prepared by subjecting finely shredded peat moss to the action of gaseous hydrogen chloride, and subsequently expelling the latter from the residual product, when examined as to its digestibility and feeding value, gave results indicating that it can only be classed as a low-grade fodder.—W. G.

Fruit; Chemical method for the detection of a prior frozen condition in —. W. M. Dehn and M. C. Taylor. *J. Ind. Eng. Chem.*, 1920, 12, 977—979.

WHEN fruit is frozen the sucrose present is converted rapidly into invert sugar as a result of the destruction of the membranes or tissue and the free mingling of the sucrose with inverting acids and invertase. If, therefore, the ratio of invert sugar to sucrose be determined in a fruit before and after freezing (in the laboratory) the data obtained will afford evidence as to whether or not the fruit has been frozen previously. For example, a sound apple was divided into two parts, A and B; the former was analysed directly and the latter after being frozen (in a mixture of ice and salt) for 16 hrs., thawed, and left standing for 24 hrs. The results obtained were:—

	Invert sugar.	Sucrose.	Ratio.	Percentage inversion.
A ..	0.1360	0.1073	100 : 79.1	37.47
B ..	0.2285	0.0863	100 : 37.7	

The percentage inversion is calculated from the formula: $10000(S-s) \div 100s + 1.0528s$, where the value $79.1 = S$, $37.7 = s$, and 1.052 is the ratio of molecular

weights of 2 mols. of hexoses to 1 mol. of sucrose. In the case of peaches the percentage inversion value is 8.93—12.00. This percentage inversion value decreases when the fruit has been frozen previously.—W. P. S.

Vitamins; Nomenclature of —. J. C. Drummond. *Biochem. J.*, 1920, 14, 660.

It is proposed to drop the final "e" of Funks' word *vitamine*. This removes most of the objections to the original term and classifies the substances as of undefined constitution. The various vitamins are conveniently referred to as vitamin A, B, C, etc. —J. C. D.

Vitamin A; Technique of feeding tests on —. J. C. Drummond and K. H. Coward. *Biochem. J.*, 1920, 14, 661—664.

THE method employed by the authors for routine testing is described. Great emphasis is laid on the purity of the basal diet with regard to the A vitamin.—J. C. D.

Vitamin A; Nuts as source of —. K. H. Coward and J. C. Drummond. *Biochem. J.*, 1920, 14, 665—667.

THE common varieties of edible nuts appear to be of little value as sources of the fat-soluble vitamin A.—J. C. D.

Vitamin A; Value of animal and vegetable oils and fats as sources of —. J. C. Drummond and K. H. Coward. *Biochem. J.*, 1920, 14, 668—677.

No hard and fast line can be drawn between these two classes of oils and fats when their value as sources of the fat-soluble vitamin A is considered. Certain vegetable oils, as for example palm and yellow maize oils, are in the crude condition good sources of the vitamin. The presence of yellow lipochrome pigments, formerly believed to be an indication of the presence of the vitamin, is now found unreliable for this purpose. The diet of an animal is an important factor governing the food value of the fat derived from that animal. Both animal and vegetable oils and fats tend to lose vitamin A on refining.—J. C. D.

Enzymes. König. See XVIII.

Butter fat. Reilly and Hickinbottom. See XXIII.

Proteins. Fearon. See XXIII.

PATENTS.

Preserving potatoes and the like vegetable substances; Process for —. Wanquier et Cie. E.P. 137,808, 30.6.19. Conv., 15.1.19. (Cf. E.P. 122,422; J., 1920, 382 A.)

VEGETABLE material is scraped, shredded, or otherwise comminuted and deprived of its moisture in a perforated drum centrifuge, filter-press, or strainer. The liquid obtained is passed through a non-perforated drum centrifuge to remove suspended matter, or is allowed to settle. The solids obtained in the second operation are added to those obtained in the first, and the whole is desiccated.—J. H. J.

Milk-fat; Manufacture of —. E. B. Phelps, A. F. Stevenson, and J. C. Baker, Assrs. to A. W. Johnston. U.S.P. 1,354,683, 5.10.20. Appl., 26.6.19.

MILK is separated and the cream washed first with water and then with acidulated water to render the emulsion unstable and the fat particles capable of coalescence. The fat and acid wash water are then separated.—J. H. J.

Protein and phosphate of calcium and magnesium from acid yeast waters; Process of recovering —. A. Giesecke. U.S.P. 1,354,822, 5.10.20. Appl., 10.3.19.

THE acid waste waters from corn (maize) steeping are partially neutralised, with the result that a combination of protein and calcium and magnesium phosphates is precipitated.—J. H. J.

Bran; Production of albumin and fat suitable for fodder from —. Versuchs- und Lehranstalt für Brauerei in Berlin. G.P. 324,122, 9.5.18.

IN order to liberate the albumin and fat from the aleurone cells in bran, it is boiled for about 5 mins. with sulphuric acid (5%) or hydrochloric acid (20%) or with alkali, under which treatment the cell-walls swell, after which slight pressure suffices to burst them.—W. J. W.

Fodder; Manufacture of — from straw. Veredelungsges. für Nahrungs u. Futtermittel. G.P. 324,648, 19.5.18. Addn. to 305,641 (J., 1919, 789A).

THE constituents dissolved from straw which has been treated as described in the original patent are precipitated, and the whole mass, freed from salts, is used as fodder.—C. A. M.

Straw or similar material; Treatment of — for fodder production. Veredelungsges. für Nahrungs- und Futtermittel. G.P. 324,893, 23.10.18. Addn. to 305,641 (J., 1919, 789 A).

IN the process described in the original patent, deep digesting vessels are used, and dilute alkaline liquors are employed, to admit of the complete immersion of the straw without undue consumption of alkali. For 1 pt. of straw, 16 pts. of 1% caustic soda liquor is used, the waste liquor being regenerated by addition of 0.06 pt. of sodium hydroxide. The consumption of sodium hydroxide after four treatments amounts to 8% of the straw.—W. J. W.

Fodder containing calcium chloride; Manufacture of — from straw etc. O. Demisch. G.P. 324,828, 16.5.18.

CHOPPED straw etc. is treated with hydrochloric acid and neutralised with calcium carbonate, and the mass dried by heat until suitable for grinding, and stored for 2—3 months. The dry product should contain about 80 g. CaCl₂ per kg.—C. A. M.

XIXB.—WATER PURIFICATION; SANITATION.

Waters; Relationship of hydrogen ion concentration to carbon dioxide content in natural —. R. E. Greenfield and G. C. Baker. *J. Ind. Eng. Chem.*, 1920, 12, 989—991.

FAIRLY accurate calculations of the hydrogen ion concentration of natural waters can be made from the simple mass law equation of the primary ionisation of carbonic acid, $(H^+)(HCO_3^-)/(H_2CO_3 + CO_2) = 3.0 \times 10^{-7}$ (Landolt and Börnstein's formula) or $(H^+)(CO_3^{--})/(HCO_3^-) = 6.0 \times 10^{-11}$ (Auerbach and Pick's formula). When carbon dioxide and bicarbonate are determined and expressed in terms of c.c. of CO₂ per litre, $(H^+) = 3.5 \times 10^{-7} CO_2 / (HCO_3^-) = 1 \times 10^{-8}$.—W. P. S.

Water softening with permutite. R. Mezger. *J. Gasbeleucht.*, 1920, 63, 644—648.

A SOLUTION of magnesium chloride corresponding to a hardness of 18° was passed through a tall cylinder of 1.2 l. capacity filled with sodium permutite at the rate of 1.1 l. per hr. for 100 hrs., and the filtrate was tested for hardness. At first all the magnesia was retained, but after 25 hrs. it began to come through, increasing rapidly at first

and then more slowly, until after 70 hrs. the filtrate had regained the original hardness. The filter then contained magnesium permittite and was used for the treatment of a solution of calcium chloride of 21° hardness. From the first magnesia came through in gradually decreasing quantity, until after 70 hrs. it had all been removed. Calcium did not appear in the filtrate until 18 hrs. had elapsed, after which it came through in increasing amounts until the original hardness was reached. The filter was then reconverted to sodium permittite and equivalent amounts of magnesia and lime were applied together to the filter. Magnesia began to come through after 26 hours and lime after 51 hours. Similar results were obtained with Stuttgart water containing lime and magnesia hardness. The experiments show that it would be possible to remove magnesia hardness with certainty by this method and thus prevent the formation of boiler-stone, which consists of magnesium carbonate, magnesium hydroxide, and calcium carbonate.—J. H. J.

Disinfection processes; Specific —. II. *Action of salts and ions on bacteria*. P. Eisenberg. *Centr. Bakt.*, 1918, I., 82, 69—208.

EXTENSIVE experiments on the action of salts on gram-positive and gram-negative bacterial species show that the toxicity of salts may be regarded principally as an additive function of the toxicities of the component ions, although purely molecular actions are not to be excluded. In evaluating antiseptics it is necessary to employ a number of representative bacterial species. (*Cf.* J.C.S., Dec.)

T. H. P.

Disinfecting values of the three isomeric cresols. F. Diithorn. *Centr. Bakt.*, 1918, I., 82, 483—491.

m-CRESOL outstrips its two isomerides in germicidal power, which is not very marked with bacterial suspensions in salt solution and bouillon, but is considerable with liquids containing proteins. Of the two other isomerides, the ortho-compound possibly has a slightly greater action than the para-compound. In practice 2—2.5% solutions of the mixed isomerides are used and the differences observed are then of little importance.—T. H. P.

Toxicity [to micro-organisms] and chemical potential. W. L. Miller. *J. Phys. Chem.*, 1920, 24, 562—569.

THE toxicity of a solution containing phenol and an indifferent salt depends primarily on the chemical potential of the phenol in the solution. Two solutions have the same toxicity when they are in equilibrium with the same solution of phenol in an immiscible solvent such as toluene or kerosene. Complications may arise from the toxicity of the salts themselves, or in dilute solutions from the plasmolysis of the cell, independently of the toxicity of the solutions employed. One or two individual cases do not fall under these heads and need further study. The observation of Paul and Krönig that solutions of mercuric chloride in aqueous alcohol show a maximum of toxicity when the ratio of alcohol to water in the solution is 1 to 3 affords another illustration of the principle, since Laird has shown that the solubility of mercuric chloride in aqueous alcohol passes through a minimum at the same ratio.—J. R. P.

Toxicity towards anthrax and staphylococcus of solutions containing phenol and sodium chloride. J. S. Lemon. *J. Phys. Chem.*, 1920, 24, 570—584.

EXPERIMENTS with anthrax spores showed that the increased toxicity of phenol observed when salt is added to its solution is in accordance with the assumption that two solutions of phenol, with or without salt, are equally toxic if their compositions

are such that both would be in equilibrium with the same solution of phenol in toluene (*cf. supra*). Experiments with staphylococcus, in which lower concentrations of phenol were used, showed that while the assumption is in fair accord with the behaviour of 0.80% phenol, in the case of 0.60% phenol the chemically equivalent solution containing salts is much less toxic; 0.70% phenol occupies an intermediate position.—J. R. P.

Iodine; Use of — for disinfecting the skin. J. Seedorf. *Act. Chirurg. Skand.*, 1920, 52, 436—483. *Chem. Zentr.*, 1920, 91, IV., 516.

IX experiments upon the sterilising action of iodine upon liquid cultures of *S. pyogenes aureus* and tetanus bacilli, the best results were obtained by the use of a solution of iodine (up to a maximum of 1%) in 50% propyl alcohol. A solution of iodine in 96% alcohol also gave good results, whilst aqueous and ethereal solutions were nearly as effective, but a solution in benzene had only a slight sterilising action.—C. A. M.

Wood; Regularities in the preservation of —. *Poisoning action of inorganic compounds (salts) on fungi*. F. Moll. *Centr. Bakt.*, 1920, II., 51, 257—279.

THE results of experiments on *Penicillium glaucum* show that the poisonous action of salts is an additive property of the ions, the poisonous ions arranged in the order of diminishing activity, being: mercury, silver, cadmium, cyanogen, copper, zinc, iron, cobalt, chromium, fluorine. Most acid ions and the ions of the alkali and alkaline-earth metals, magnesium, and aluminium may be regarded as inactive in this respect. (*Cf.* J.C.S., Dec.)

—T. H. P.

“*Pickering*” {*fungicidal*} *sprays [for plants]*. F. C. Cook. *J. Franklin Inst.*, 1926, 190, 571.

“*PICKERING*” sprays prepared by mixing dilute solutions of copper sulphate with saturated lime-water (J., 1912, 196) were twice as effective upon potato plants as the ordinary Bordeaux mixture, per unit of copper present. The sprays adhered to the leaves equally well and had no injurious effect upon hardy foliage. Satisfactory results were also obtained with a spray in which the lime-water was replaced by baryta-water.—C. A. M.

Copper; Non-toxicity of — for moulds in general and for mildew in particular. G. and G. Villedieu. *Comptes rend.*, 1920, 171, 737—739.

IT was found that copper compounds (sulphate, hydrated oxide) in the presence of citric or tartaric acid are not toxic for *Peronospora* when grown on nutrient agar.—W. G.

Tobacco and other vegetable substances; Conversion of air into a lethal mixture of gases by storage of —. R. C. Frederick. *J. Hyg.*, 1920, 19, 205—207.

SAMPLES of air drawn from a storeroom containing a large quantity of tobacco in a mouldy condition showed an abnormally high content of carbon dioxide, *viz.*, 2.27%. Experiments in which samples of tobacco of varying physical condition were kept in bottles with vaselined stoppers secured by rubber bands showed that wet tobacco kept in an unventilated store is liable to convert the air into a lethal mixture of gases; mouldiness is not a causative agent, but accelerates the reaction, and heat increases the decomposition. For example, in one experiment the air from a bottle in which wet mouldy tobacco had been kept for 18 days at 12° C. and 37° C. contained respectively 49.95 and 39.85% of CO₂ and 1.021 and 0.29 O₂. With dry tobacco containing less than 10% of moisture a

dangerous amount of carbon dioxide was not formed even after 32 days. The effect is independent of materials added to tobacco in course of manufacture. It was further found that wet hay and potatoes which had been inoculated with mould were deleterious. After 18 days' storage at 12° and 37°, the air from the sample of hay contained 21.92 and 24.83% CO₂, and 0.25 and 0.26% O₂, whilst that from potatoes after 40 days at 12° C. indicated 21.21% CO₂ and 0.21% O₂. In no instance was carbon monoxide or other combustible gas generated.—W. J. W.

Carbon tetrachloride fire extinguishers; Poisonous gases from —. A. C. Fieldner, S. H. Katz, S. P. Kinney, and E. S. Longfellow. J. Franklin Inst., 1920, 190, 513–565.

As a result of a fatal accident from the use of a carbon tetrachloride fire extinguisher in a confined space, experiments were made with pure carbon tetrachloride and the liquids contained in fire extinguishers. When the liquid was poured on to a fire or hot iron in a closed chamber, or the vapour was passed, together with air, through an iron or quartz tube heated to 600°–800° C., toxic quantities of phosgene (12.3–13.8%) and chlorine (12–20%) and smaller amounts of hydrogen chloride (5.6–11.9%) were formed; the figures represent percentages of the original carbon tetrachloride present in the decomposition products. In some of the tube experiments half of the carbon tetrachloride was decomposed. The presence of turpentine reduced the amount of chlorine liberated from the carbon tetrachloride, but had little, if any, inhibiting effect on the phosgene. It is recommended that carbon tetrachloride fire extinguishers should not be used under conditions where the fumes would be breathed. Efficient protection is afforded by the Army (U.S.A.) type of gas mask. (*Cf.* J.C.S., Dec.) —C. A. M.

Typhus and paratyphus bacteria. Stern. See XVIII.

PATENTS.

Softening water; Process of and apparatus for —. T. R. Duggan, Assr. to The Permutit Co. U.S.P. 1,354,604, 5.10.20. Appl., 26.9.17.

In softening water by filtration through a bed of base-exchanging material contained in a closed filter, occasional sudden pulsations are communicated to the water in the filter which are sufficiently energetic to cause a disturbance of the base-exchanging material.—J. H. J.

Filtering compound. L. W. Shull, Assr. to Allen Filter Co. U.S.P., 1,336,591, 13.4.20. Appl., 1.11.16.

FILTERS for removing germs from water or blood serum are made from a mixture of kieselguhr, asbestos, and a third substance, *e.g.*, whiting, lime, alumina, magnesium chloride, or the like. The materials are intimately mixed to a slip with water, moulded or cast, and fired at a high temperature.

Filter for the purification of water. Radiorex, G.m.b.H., Ver. Magnesia-Co., and E. Hildebrandt, A.-G. G.P. 300,051, 9.11.13.

The filtering medium consists either wholly or partly of a radioactive substance, such as pitchblende. The filter does not become useless by reason of an accumulation of water bacteria, and has a long life.—A. R. P.

Disinfectants; Manufacture of —. A. Hahn and M. Federer. G.P. 322,739, 29.6.11.

DERIVATIVES of laminaric acid are mixed with disin-

fectants in aqueous solution, the proportion of the disinfectant not being appreciably in excess of that required for sterilising the laminaric acid derivative. The sodium-ammonium salt of laminaric acid increases the disinfectant properties of sodium fluoride, mercuric chloride, and formaldehyde.

—W. J. W.

Drying trough. G.P. 323,462. See I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Opium preparations of the type of "pantopon"; Determination of subsidiary alkaloids and also of narcotine and papaverine in —. E. Anneler. Arch. Pharm., 1920, 258, 130–137.

To determine the total alkaloids other than morphine, 1.5 g. of the mixed hydrochlorides is dissolved in 8 c.c. of water, treated with 90 g. of benzene and 0.5 g. of sodium carbonate, shaken at intervals during $\frac{1}{2}$ hr., and then treated with 5 g. of anhydrous sodium sulphate and 0.5 g. of powdered tragacanth. After the solid matter has settled the liquid is filtered, and an aliquot part is evaporated to dryness, redissolved in alcohol, and again evaporated. To separate the narcotine from the other bases it is converted into sodium narcotinate. The mixture obtained as above is dissolved in 6 c.c. of benzene, treated with 1 c.c. of alcoholic potassium hydroxide solution, allowed to stand for $\frac{1}{2}$ hr. with frequent shaking, and then the benzene solution is shaken in a separating funnel with successive quantities of sodium hydroxide solution, and the united aqueous extracts are repeatedly shaken with small quantities of chloroform. To regenerate the narcotine the alkaline solution is neutralised with hydrochloric acid, made up to 100 c.c., heated with 3 c.c. of concentrated hydrochloric acid for 20 mins. at 80°–90° C., cooled rapidly, treated with an excess of sodium carbonate solution, and shaken out with benzene or chloroform. To determine the papaverine the combined benzene and chloroform extracts, obtained in separating the narcotine, are evaporated to dryness. The residue is dissolved in 10 c.c. of water and 1 c.c. of hydrochloric acid, filtered, treated with a 2% ammonia solution, drop by drop, and stirred meanwhile, until a slight permanent turbidity appears, and then, after addition of 2 g. of sodium acetate, left to stand for 24 hrs. The papaverine is collected on a filter, redissolved in warm alcohol, and the solution evaporated to dryness.—J. H. L.

Glucosides. VII. Constitution of amygdalin. P. Karrer, C. Nägeli, and L. Lang. Helv. Chim. Acta, 1920, 3, 573–583.

HEPTA-ACETYLCELLOSIDOMANDELIC acid, obtained in small quantities by the interaction of inactive silver mandelate and acetobromocellobiose, is not identical with hepta-acetylamygdalinic acid, hence the corresponding non-acetylated acids are not identical, and the unknown disaccharide of amygdalin cannot be cellobiose; the β -glucosidic nature of the union of the disaccharide in the two cases is shown by the fact that hydrolysis is effected by emulsin in either case. (*Cf.* J.C.S., Dec.)—T. H. P.

Phosphatides; Preparation of — from coloured plant organs. R. Fritsch. Z. physiol. Chem., 1919, 107, 165–176.

VARIOUS plants containing chlorophyll and other plant pigments have been examined for their phosphatide content. Only a small part of the total phosphorus could be traced to the phosphatides of the plants. In the leaves of the maple the phosphatide-phosphorus amounted to 4.78%, in the

leaves of the ash to 3.46% of the total phosphorus. No calcium inosinate was found in the green assimilating organs. In order to obtain phosphatides with the theoretical content of phosphorus, large quantities of tissue must be employed. In grass stored in silos the phosphatides are almost entirely decomposed.—S. S. Z.

Guanidine; Preparation of — by the interaction of dicyanodiamide and ammonium thiocyanate. E. A. Werner and J. Bell. Chem. Soc. Trans., 1920, 117, 1133–1136.

PURE guanidine thiocyanate was readily obtained in 90% yield by melting together dicyanodiamide (43.5 g. of 95.5% purity) and ammonium thiocyanate (76 g.), and maintaining the mixture at 120°C. for about 3½ hrs. Depolymerisation of the dicyanodiamide is the first phase of the reaction, which is expressed by the equation: $C_2H_4N_4 + 2NH_4SCN \rightarrow 2CH_3N_3HSCN$. A subsidiary reaction results in the formation of thioammeline, which is, however, readily separated by digesting the reaction mixture, without previous cooling, with 250 c.c. of water, and filtering, thioammeline (7–8 g.) separating as an amorphous residue. The filtrate, after concentration as far as possible at 100°C., sets to a crystalline mass of guanidine thiocyanate, which may be further purified by recrystallisation from water. —G. F. M.

Salvarsan; Colloidal properties of aqueous solutions of —. Z. Klemensiewicz. Bull. Soc. Chim., 1920, 27, 820–824.

THE viscosity of aqueous solutions of salvarsan depends on the concentration of the solution, the length of time it has been prepared, the temperature at which it has been kept, and the presence of acids or alkalis. (Cf. J.C.S., Dec.)—W. G.

Acetylsalicylic acid; Melting point of —. G. Cappelli. Giorn. Chim. Ind. Appl., 1920, 2, 291–300.

WHEN heated in a capillary tube immersed in a bath, acetylsalicylic acid begins to melt in contact with the walls of the tube at 132°C. and becomes completely transparent only at 135°. (Cf. J., 1919, 157A.)—T. H. P.

Benzyl alcohol; Stability of solutions of —. D. I. Macht and A. T. Shohl. J. Pharm. Exp. Ther., 1920, 16, 61–69.

SOLUTIONS should be preserved in non-soluble glass containers if deterioration is to be prevented. —J. C. D.

Lachrymatory power of irritant substances; Measurement of the —. C. Dufraisse and J. C. Bongrand. Comptes rend., 1920, 171, 817–819.

IF C_1 be the concentration of benzyl bromide, and C_2 that of the substance under examination, required in an atmosphere just to produce an irritant action on the eyes at the end of 30 secs., the lachrymatory power is given by C_1/C_2 , that of benzyl bromide being taken as unity. The following values were obtained: Benzyl iodide 2, bromoacetone 1.8, sym-dibromomethyl oxide 1/4, chloropierin 1/6, chloroacetone 1/8, acrolein 1/10.—W. G.

Carbon bisulphide; Interaction of — with ammonium carbonate. F. A. Gilfillan. J. Amer. Chem. Soc., 1920, 42, 2072–2079.

CARBON bisulphide and ammonium carbonate react at 160°C. to give a mixture of ammonium thiocyanate and thiourea, the equilibrium depending upon the concentration of the reagents, the temperature and duration of heating, and the concentration of the hydrogen sulphide produced in

the reaction. The latter favours the reversion of the thiocyanate to thiourea. The yields of thiourea are much below those obtained by direct heating of ammonium thiocyanate. Ammonium thiocyanate cannot be estimated accurately by the indirect titration method (Krall, Chem. Soc. Trans., 1913, 103, 1385) in the presence of more than 15% of thiourea, but direct titration with silver nitrate may be used with mixtures containing as much as 40% of thiourea. In solutions containing not more than 5 mg. of thiourea per 100 c.c. this substance may be estimated by titration with iodine.—W. G.

Glycerol substitutes (per- and perka-glycerol); Alkali lactates as —. C. Neuberg and E. Rein-furth. Ber., 1920, 53, 1783–1791.

THE technical uses of glycerol, apart from the production of explosives, depend on its viscosity, hygroscopicity, and neutrality; these properties are also exhibited by aqueous solutions of sodium and potassium lactates (per- and perka-glycerol respectively), which have been extensively used by the belligerent forces of the Central Powers and for medical and cosmetic purposes during the late war. Economically, their preparation permits a much better utilisation of the initial material (sugar etc.), since this can be fermented so as to yield 95% and more lactic acid, whilst, on the technical scale, it only gives one-fifth to a quarter of its weight of glycerol; further, for many purposes, the glycerol substitutes can be used in considerably more dilute solution than glycerol itself. The paper contains an extended series of tables and graphs showing the relationship between specific gravity and concentration of aqueous solutions of per- and perka-glycerol at 15°C., the freezing point of solutions of per-glycerol at different concentrations, the comparative freezing point of equimolar solutions of per-glycerol and glycerol, the boiling points of solutions of per-glycerol, the comparative hygroscopicity of solutions of glycerol and per-glycerol at 25°C., and the viscosity of per-glycerol. (Cf. J.C.S., Dec.)—H. W.

Ethylene bromohydrin; Preparation and characterisation of —. J. Read and R. G. Hook. Chem. Soc. Trans., 1920, 117, 1214–1226.

PURE ethylene bromohydrin may be prepared in quantity by the action of ethylene on cold dilute bromine water. Under favourable circumstances the molecular ratio of ethylene bromohydrin to ethylene dibromide formed is 10:1, or even higher in very dilute solutions, but the ratio decreases continuously with increasing concentration of bromohydrin and hydrogen bromide in the solution and also with rise of temperature. The reaction is accelerated by cooling and also by sunlight. Ethylene bromohydrin may be distilled without change *in vacuo*, but at ordinary pressures it decomposes considerably at its boiling point. It has sp. gr. 1.7629 at 20°/12°C., and $n_D^{20} = 1.4915$. It forms with water a mixture of constant b.p. (99.1°C. at 762.4 mm.) at a concentration of 35%. Ethylene bromohydrin is hydrolysed more readily than the chlorohydrin, hydrolysis being perceptible, although extremely slow, in cold aqueous solutions.—G. F. M.

Acetoneglycerol. Fischer and Pfähler. See XII.

PATENTS.

Esters; Apparatus for the manufacture of —. U.S. Industrial Alcohol Co., Assees. of A. A. Backhaus. E.P. (a) 130,969, and (a) 130,970, 23.6.19. Conv., 7.8.18.

CLAIM is made to apparatus for carrying out the process described in E.P. 130,968 (J., 1920, 674A), using sulphuric acid, alcohol, and (a) a dilute organic acid, e.g., vinegar, or (b) a concentrated organic acid, e.g., glacial acetic acid.—L. A. C.

Trimethylacetylsalicylic acid compounds. W. Grüttefen, Assr. to Alien Property Custodian. U.S.P. 1,338,297, 27.4.20. Appl., 27.4.19.

TRIMETHYLACETYSALICYLIC acid (CH_3)₃C.CO.O. C_6H_4 .COOH, white leaflets, m.p. 135° C., is prepared by the interaction of salicylic acid and trimethylacetyl chloride in ether and pyridine. Trimethyl-*m*-cresotic acid, prepared in an analogous manner, melts at 160° C. These acids, both in the free state and as salts, are of value as antirheumatics, analgesics, and diuretics.

Amylodextrin and silicic acid; Manufacture of colloidal preparations of —. Lecinwerk E. Laves. G.P. 323,596, 12.3.19.

SILICIC acid is produced in an aqueous solution of amylo-dextrin by the decomposition of silicates with acids, or by hydrolysis of esters of silicic acid or halogen compounds of silicon. The product is precipitated by alcohol or acetone, and dried at a low temperature. Solutions containing less than 1% of silicic acid may be sterilised without gelatinisation by passing a current of steam through for several hours. The amylo-dextrin compounds, both in the solid state and in sterilised solution, are suitable for therapeutic purposes.—W. J. W.

Amylo-dextrin and calcium phosphate, or calcium sulphate; Manufacture of colloidal preparations of —. Lecinwerk E. Laves. G.P. 323,783. 31.10.18.

CALCIUM phosphate or calcium sulphate is formed by double decomposition in an aqueous solution of amylo-dextrin, or of carbohydrates containing it, the amylo-dextrin compound produced being then separated by precipitation with an organic solvent, or by careful evaporation of the solution *in vacuo* at a low temperature. The calcium phosphate compound consists of tricalcium-phosphate-amylo-dextrin. The products have a therapeutic application.—W. J. W.

Oils, resins, waxes, balsams, and extracts; Method for converting — into dry powders. R. Marcus. G.P. 323,908, 8.10.15.

THE materials are mixed with gelatinous silicic acid, and the mixture is allowed to dry under moderate heat. Smooth powders are thus produced with 1 pt. of silicic acid and 2 pts. of *Oleum rosei*, or 1.4 pts. of protargol, or 2.5 pts. of lemon oil.

—W. J. W.

Glycerophosphate solution; Conversion of — into a crystalline preparation. P. Bergell. G.P. 324,029, 1.4.19.

A CONCENTRATED solution of sodium glycerophosphate is treated with partly dehydrated disodium hydrogen phosphate in such quantity that the water in the solution does not exceed the water of crystallisation removed from the salt. When dried by exposure to the air the mass is a crystalline powder containing 7 mols. of water. It has a pleasant taste, and can be compressed into tablets for therapeutic use.—C. A. M.

Pinacone; Process for the manufacture of —. Farbenfabr. vorm. F. Bayer und Co. G.P. (A) 324,919, 8.5.17 (Addn. to 306,523; J., 1919, 158 A), and (B) 324,920, 13.9.18.

(A) In the process described in G.P. 306,523, the use of cathodes of an alloy of 90% Pb and 10% Sn, or of brass or bronze, yields a product containing pinacone and isopropyl alcohol in a ratio of about 10:1. (B) Acetone is reduced in alkaline solution using graphite electrodes. The product contains 70% of pinacone and 10–15% of isopropyl alcohol.

—L. A. C.

Double compound containing quinine; Process for the manufacture of a —. A. C. Röttinger. G.P. 325,156, 22.11.18.

THE double compound, which has a bitter, acid taste, but does not show the after-taste or bad effects of quinine, is prepared by the interaction of equimolecular proportions of quinine, tartaric acid, and hexamethylenetetramine in alcoholic solution.

—L. A. C.

Phenylated aminohydrindenecarboxylic acid; Process for the manufacture of a —. Chem. Werke Grenzach A.-G. G.P. 325,713, 29.6.18.

THE condensation product from α -hydrindone and isatin, a colourless powder of m.p. above 295° C., is reduced in boiling amyl alcohol with metallic sodium, and the sodium salt produced is subsequently converted to the free phenylated aminohydrindenecarboxylic acid. The crystalline acid, which has therapeutic value, contains 76.43% C and 6.1% H, softens with red coloration and liberation of carbon dioxide at 140° C., and melts at 180° C.; the hydrochloride has m.p. 205° C.

—L. A. C.

N-Methylhexamethylenetetramine; Process for producing salts of —. R. Tschunke, Assr. to The Chemical Foundation, Inc. U.S.P. 1,336,709, 13.4.20. Appl., 19.1.14. Renewed 26.6.19.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic sensitisers; Studies on —. II. The carbocyanines. W. H. Mills and W. J. Pope. Phot. J., 1920, 60, 253–266.

THE carbocyanines are produced by the condensation of 2 mols. of a quinaldine alkyl iodide with 1 mol. of formaldehyde under the influence of alkalis. The formula adopted for the class assumes the linkage :CH.CH:CH. between the two quinaldine residues, attached at the 2 position in each case, thus: $\text{N(R).C}_6\text{H}_4\text{:CH.CH:CH.C}_6\text{H}_4\text{.N.R.X}$, the simplest member being the 1.1'-dimethyl compound. Sensitol Red (German, Pinacyanol) is 1.1'-diethyl-carbocyanine iodide, and is, so far, the most important dye of the class. Eighteen members of the series are described both as to their chemical properties and as to their sensitising as determined by the method previously described (J., 1920, 468 A). The change from the 1.1'-dimethyl to the 1.1'-diethyl compound is accompanied by a considerable increase in sensitising action; further increase in the weight of the substituent groups in these positions results in a steady decrease of sensitising action. The effect of introducing substituent groups in other positions in the molecule varies with the nature of the group and the position. Generally speaking there is a reduction of sensitising action as compared with the 1.1'-compound, which increases with the size of the substituting groups. Substitution in the 6-6' positions has a slight reducing effect, in the 5-5' positions a strong reducing effect. It is suggested that the distinguishing characteristic of the carbocyanines as compared with the isocyanines (*loc. cit.*) and on which the extension of their sensitising action into the far red depends is not the position of attachment to the

quinaldine residues, but the presence of the linkage :CH.CH:CH. instead of :CH.—B. V. S.

Neutral-wedge photometer; New —, for sensitometry for photographic copying processes, and scientific light-measurement. J. M. Eder. Phot. Korrr., 1919, 56, 244—271.

This is an adaptation of a Goldberg neutral wedge in combination with a special form of millimetre scale. In one form a wedge 9×12 cm. is used having a constant of 0.40137 per cm. and being provided also with colour strips, red, yellow, green, and blue, for the testing of chromatic and panchromatic plates; another form is 16×3 cm. with a constant of 0.30484 per cm., this being chiefly intended for actinometric and similar work. The use of wedges in sensitometry, in photometry, and in actinometry is described and tables are given showing the relative proportions of light absorbed at all points of the wedge, comparing the wedge scale readings with Scheiner scale numbers, giving comparative results obtained by the wedge with Hefner and electric light for speeds of ordinary and colour-sensitive plates, etc. There is also a comparison of the various types of actinometer papers which may be used.—B. V. S.

Eder-Hecht neutral-wedge photometer for sensitometry and light-measurement. II. Magnesium as a secondary standard light source. J. M. Eder. Phot. Korrr., 1920, 57, 1—9, 41—44, 83—86.

THE use of magnesium light as a secondary standard light source is advantageous by reason of its simplicity and its approximation, in colour value, to average daylight. A suitable unit is 2 mg. at a distance of 3 m., which is approximately equivalent to a Hefner-candle-metre-minute. The magnesium, about 3 mm. of ordinary ribbon, is held on the point of a steel needle at the correct distance from the plate to be exposed. The use of the Eder-Hecht photometer (*cf. supra*) with magnesium as the light source is fully described, comparative results with the Hefner lamp for various plates being given as well as sundry tabulated constants of the wedge. A full scheme for testing and evaluating plates and papers with the aid of the wedge is described and also the use of the wedge for evaluating exposures in light-therapy.

—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitro-derivatives of toluene. Brady and Williams. See III.

PATENTS.

Ammonium nitrate explosives; Manufacture of —. E. Müller. E.P. 152,199, 2.10.19.

To obtain from mixtures of ammonium nitrate and a hydrocarbon, such as petroleum, explosives which are insensitive to concussion but yet can be readily detonated, the constituents are melted together under a pressure of $\frac{1}{2}$ to 1 atm. Other ingredients may be added. Suitable mixtures are: ammonium nitrate, 94%; petroleum, 6%; ammonium nitrate, 92%; woodmeal, 1%; petroleum, 7%; ammonium nitrate, 95%; paraffin, 5%; ammonium nitrate, 93%; phenol, 7%.—W. J. W.

Propellant powder and process of making same. C. I. B. Henning, Assr. to E. J. du Pont de Nemours and Co. U.S.P. 1,336,463, 13.4.20. Appl., 23.8.19.

A POWDERED metal capable of reducing metallic fouling, e.g., tin or a tin-lead alloy, is incorporated with nitrocellulose powder during the process of manufacture.

Granulated "safety" explosives; Manufacture of —. Oberschlesische Sprengstoff-A.-G. G.P. 298,448, 16.12.16.

EXPLOSIVES of a dusty nature, and which can be detonated only with difficulty, may be converted into granular safety explosives, which can be readily detonated, by mixing them with finely-divided, fusible carbonaceous substances such as naphthalene, resin, or dextrin, and agitating the mixture with steam.—W. J. W.

Chlorate explosives; Manufacture of —. G. A. Krause und Co., A.-G. G.P. 299,630, 23.1.17.

A CHLORATE solution containing in suspension charcoal or other material is evaporated by ejecting it from the evaporating vessel in the form of a spray and directing against the outside of this a stream of gaseous drying agent. An intimately mixed, granular powder is thus obtained without danger.—W. J. W.

[Smokeless powder;] Process for drying [—] by means of hot air. K. Himpel and A. Besler. G.P. 301,607, 3.4.17. Conv., 17.2.16.

THE air used for drying explosives is cooled to a definite temperature, and the condensed solvent is completely separated by mechanical means. The content of condensable vapour in the air can thus be accurately adjusted.—W. J. W.

Nitrocellulose; Manufacture of —. Deutsche Gasglühlicht A.-G. (Auerger.). G.P. 302,494, 1.12.16.

AFTER nitration of the cellulose, the bulk of the waste acid is displaced by sulphuric acid of 55°—60° B. (sp. gr. 1.616—1.712), previously cooled to 0° C. Up to 80—90% of the nitration acid is recovered as waste acid, from which nitric acid of commercial strength is obtainable.—W. J. W.

Pyrotechnics [; Compositions for —]. A. Brock. E.P. 152,529, 3.11.19.

HEXAMETHYLENETETRAMINE, or its salts, is substituted for, or added to, the usual combustibles, such as charcoal, shellac, dextrin, sugar, and oil, in fire-work compositions, specially for indoor displays.

—W. J. W.

XXIII.—ANALYSIS.

Anemometer; Directional hot wire —. J. S. G. Thomas. Phil. Mag., 1920, 40, 640—665.

THE directional hot wire anemometer consists of two fine wires mounted parallel and one behind the other in juxtaposition, transversely to the direction of flow of the gas in the pipe or channel. The wires constitute two arms of a Wheatstone bridge the remaining arms of which are formed of a resistance of 1000 ohms and an arm capable of adjustment. A constant current is maintained in the bridge and the battery terminals are connected through a rheostat with the appropriate ends of the platinum wires so that the maximum heat is developed in these wires. As the velocity of the gas stream to which the heated wires are exposed is gradually increased from zero, the galvanometer deflection increases until a critical value of the gas stream is attained. With further increase of the impressed velocity of the gas stream the galvanometer deflection slowly diminishes; on reversing the direction of flow of the gas current the galvanometer deflection is reversed. The relative sensitiveness of the instrument has been investigated with the wires in different positions, and the connexion between the critical velocity and the heating current and the diameter of the wires is also dealt with. (*Cf. J.*, 1918, 165 r.)—J. F. S.

Analysis; Qualitative chemical — V. Macri.
Boll. Chim. Farm., 1920, 59, 385—389.

The following scheme serves for the detection of the metals in solution. The solution is neutralised with ammonia solution, treated successively with ammonium sulphide and carbonate, and allowed to digest on a water-bath with occasional stirring. A small portion of the liquid is tested with the above reagents (to ensure that they are in sufficient quantity) and with ammonium phosphate; if a precipitate forms, more of the reagent is added. The filtrate or solution is rendered acid with hydrochloric acid and any precipitate tested for As, Sb, Sn, Pt, Au; the filtrate is evaporated to dryness and tested for K, Na, Li. The original phosphate precipitate is washed with water containing hydrogen sulphide and heated with hydrochloric acid, and the residue tested for Ag, Pb, Hg, Cu, Bi, Cd, Ni, and Co; the solution is freed from hydrogen sulphide and boiled with sodium acetate; the precipitate may contain Al, Fe, and Cr, from which the Al is separated by potassium hydroxide. The solution is treated with hydrogen peroxide, when manganese is precipitated, and the filtrate treated with sodium sulphate and alcohol. The precipitate is tested for Ba, Sr, and Ca, and the solution rendered ammoniacal and treated with phosphate; magnesium is precipitated, and zinc is tested for in the solution by means of hydrogen sulphide.

—T. H. P.

Analysis of organic compounds; Use of reduced copper in the elementary — E. Cherbuliez.
Z. anal. Chem., 1920, 59, 297—302.

At a red heat copper containing small proportions of iron or zinc causes appreciable reduction of carbon dioxide to carbon monoxide and is, therefore, unsuitable for use in the determination of hydrogen and carbon in nitrogen compounds by combustion or in the estimation of nitrogen.

—T. H. P.

Bromine; Determination of traces of — in organic matter. A. Damiens. Comptes rend., 1920, 171, 799—802.

The organic matter is dried at 100°—105° C., mixed with 5 pts. of potassium nitrate and 10 pts. of sodium carbonate and heated in a silver crucible to just short of fusion. After cooling, the mass is extracted with water and the solution filtered. In a portion of the filtrate the iodine is estimated either by Labat's method (distillation in presence of iron ammonium alum), or by precipitation as silver iodide, subsequent liberation by chlorine, and colorimetric estimation in chloroform solution. In another portion of the filtrate the whole of the halogens are precipitated as their silver salts, which are afterwards decomposed by zinc and sulphuric acid, the silver being filtered off, and the bromine estimated in the filtrate by the method of Denigès and Chelle (J., 1918, 284A). In the presence of iodide, the iodine is first removed from the last filtrate by Labat's method before the bromine is estimated. Chlorine is estimated by difference from the total halogen content.—W. G.

Distillation in steam; Applications of the method of — [Differentiating butter fat and other fats.] J. Reilly and W. J. Hickinbottom. Sci. Proc. Royal Dublin Soc., 1920, 16, 131—142.

The limitations and possibilities of the distillation method for determining molecular structure and alteration in the state of molecular aggregation are discussed. A method is given for differentiating between butter fat and other fats containing a comparatively high proportion of volatile acids; 100 c.c. of the filtered Reichert-Meissl distillate is neutral-

ised with barium hydroxide solution, the barium is then precipitated by the addition of the requisite amount of sulphuric acid, the mixture diluted to 200 c.c., and distilled from an ordinary round-bottomed flask provided with a steam-jacket. The distillate is collected in 10 g. fractions, which are titrated. The percentage of acid distilling in each fraction is calculated on the acid present in 100 c.c. of the original Reichert-Meissl distillate. Results obtained with typical fats are as follows:—

Weight of oil distillate in g.	Percentage of acid distilling in each fraction.				
	Butter fat.	Palm kernel oil.	Babassu fat.	Coconut oil.	Chemical.
10	12.5	20	25	22	22
20	23.0	35	42	38	38
30	35.5	49	57	53	53
40	42.5	60	70	65	65
50	50.0	68	80	75	75

—W. P. S.

Protein; Adamkiewicz' reaction for — Mechanism of Hopkins-Cole test for tryptophane. W. R. Fearon. Biochem. J., 1920, 14, 548—564.

The author shows that the colour tests mentioned are dependent on the formation of colour condensation products of the aldehyde present in the reagent and tryptophane. A number of these pigments have been isolated. Their properties and chemical characters are fully discussed. (Cf. J.C.S., Dec.)

—J. C. D.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

- American Metal Co. Rotary kilns. 32,359. Nov. 16. (U.S., 8.12.19.)
- Avrutik. Separation of liquids and solids. 31,582. Nov. 8.
- Barrett Co. Manufacture of carriers for catalytic material. 32,068. Nov. 12. (U.S., 13.11.19.)
- Bateman. Separators for liquids of different density. 31,575. Nov. 8.
- Beeston. Regenerative furnaces. 33,082. Nov. 24.
- Bing-Werke. Preventing boiling-over of liquids. 32,562. Nov. 18. (Ger., 2.7.19.)
- Beythe. Drying ovens or stoves etc. 32,373. Nov. 17.
- Doherty. Mixing machines. 33,276. Nov. 25.
- Emmens. Settling-tanks, storage tanks, etc. 31,597. Nov. 8.

Hoyle, Centrifugal separators. 33,179. Nov. 24.
Morgan, and Thermal Industrial and Chemical Research Co. Evaporation of liquids which deposit matter during the process or on cooling. 33,312. Nov. 25.

Muchka, Storing, conveying, etc. highly inflammable liquids. 32,337, 32,339, 32,340. Nov. 16. (Austria, 6.11.14, 19.6.16, 30.10.16.)

Muchka, Production of protective gas. 32,338. Nov. 16. (Austria, 21.9.15.)

Muchka, Production of mixtures of nitrogen and carbonic acid deficient in oxygen. 32,341. Nov. 16. (Austria, 3.12.17.)

Nelson, Kilns. 33,309. Nov. 25.

Orr, Rotary crushing and mixing mills etc. 33,517. Nov. 27.

Reid, Furnaces. 33,196. Nov. 24.

Robertson (Power Speciality Co.), Stills. 31,465-8. Nov. 26.

Sears and Twigg, Furnaces. 31,942. Nov. 11.

Skudder, Apparatus for separating powdered minerals etc. suspended in liquid. 33,571. Nov. 27.

Smallwood, Furnaces. 31,747. Nov. 10.

Soderlund, and Techno-Chemical Laboratories, Ltd. Recovery of heat from treated material. 32,127. Nov. 13.

Statincau, Catalytic process for obtaining reactions between a gas and another substance. 32,932. Nov. 22. (Switz., 22.11.19.)

Velten, Treating material by a rising fluid current. 31,616 and 31,870. Nov. 9 and 11. (Ger., 12.12.19 and 18.2.20.)

Wake, Ring pulverising-mills. 32,819. Nov. 20.

COMPLETE SPECIFICATIONS ACCEPTED.

17,451 (1919). Akt. de Norske Saltverker. Preventing formation of gypseous incrustations in evaporators etc. (131,279.) Nov. 17.

22,724 (1919). Woltersdorf, Grinding and disintegrating machines. (132,794.) Nov. 24.

25,153 (1919). Hardingham (Redman), Furnaces. (153,451.) Nov. 17.

25,729 (1919). Bollmann. *See V.*

32,582 (1919). Rosanoff Process Co. Fractionating apparatus. (137,300.) Nov. 17.

1114 (1920). Niessen, Apparatus for boiling and drying organic matter. (137,843.) Nov. 24.

9297 (1920). Lambot, Rocking-furnaces. (141,054.) Dec. 1.

10,205 (1920). Akt. Vaporackumulator, Digesters. (141,708.) Nov. 17.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Bamber and Parker, Gas-scrubbers. 32,120. Nov. 13.

Bates, Raising sp. gr. and flash-points of liquids. 31,634. Nov. 9. (U.S., 10.11.19.)

Bates, Manufacture of fuel. 32,008. Nov. 12.

Bates, Fuel. 32,262. Nov. 16.

Bates, Liquid fuel. 32,263. Nov. 16.

Bates, Mixed fuels. 33,135 and 33,501. Nov. 24 and 27.

Chandler and others. 33,036-7. *See XXIII.*

Clark and Co., and Tervet, Heat treatment of oils etc. 32,250. Nov. 15.

Cordes and Thiele, Preparation of lubricating and cylinder oils. 32,955. Nov. 12. (Ger., 24.11.19.)

Denington and Perry, Treatment of peat etc. 32,600-1. Nov. 18.

Dixon and Garton, Briquetting coal etc. 31,776. Nov. 10.

Ehrat, Production of petroleum and natural gas. 33,461. Nov. 26.

Emerson, Conversion of hydrocarbon oils. 31,555. Nov. 8. (U.S., 6.5.20.)

Foster, Vertical gas-retort etc. 32,169. Nov. 15.

Gooday, Purifying lubricating oil. 32,679. Nov. 19.

Mawson, Gas-producers. 31,931. Nov. 11.

Muchka, 32,337-33,341. *See I.*

Parr and Pearson, Desulphurising hydrocarbons etc. 32,195. Nov. 15.

Rambush, Gas-producers etc. 33,144. Nov. 26.

Robus, Apparatus for distilling peat. 31,470. Nov. 8.

Wells, Gas-producers. 31,788. Nov. 10.

Wilson, Distilling fuels, shales, etc. 32,458. Nov. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

11,419 (1919). Marks (U.S. Industrial Alcohol Co.), Non-freezing fuel. (153,925.) Dec. 1.

11,774 (1919). Doherty, Coal-carbonising furnaces. (132,489.) Nov. 17.

19,421 (1919). Kormann, Alteration of high-boiling hydrocarbons to low-boiling hydrocarbons. (153,654.) Nov. 24.

19,650 (1919). Edwards, Extracting oil from shale, coal, etc. (153,663.) Nov. 24.

19,702 (1919). Rambush, Removal of sulphur from gases. (153,665.) Nov. 24.

2718 (1920). Avellana, Wood-gas producer. (138,362.) Nov. 17.

3503 (1920). Igranic Electric Co. *See XXIII.*

9676 (1920). De Laval Separator Co. Purifying used mineral oil. (142,059.) Dec. 1.

10,390 (1920). Smith, Purifying mineral oils. (153,844.) Nov. 24.

13,888 (1920). Hulton and Neilson, Refining mineral oils. (153,857.) Nov. 24.

15,778 (1920). Lowenstein, Irinyi, and Kayser, Apparatus for low temperature distillation of coal, shale, etc. (144,712.) Dec. 1.

16,757 (1920). Meister, Lucius, u. Brüning, Manufacture of methane. (146,110.) Nov. 21.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Atack and Soutar, Manufacture of chloroamino-anthraquinone. 31,615. Nov. 9.

Atack, Oxidation of aromatic hydrocarbons. 31,971. Nov. 12.

Atack, Manufacture of anthraquinone. 33,374. Nov. 26.

British Dyestuffs Corp., Frank, Gibson, and Robinson, Manufacture of a chlorinated naphthalene derivative. 32,241. Nov. 15.

Dawson, Purification of anthraquinone. 32,286. Nov. 16.

Kolshorn, Manufacture of derivatives of *p*-aminophenol and of its *o*-alkyl ethers. 33,206-7. Nov. 21. (Ger., 12.12.19.)

Parr and Pearson. 32,195. *See II.*

Wilson, Distillation of tar and oils. 32,391. Nov. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

11,457 (1920). Kinzberger u. Co. Purification of anthraquinone. (113,885.) Nov. 17.

15,534 (1920). Kinzberger u. Co. Purification of crude anthracene. (144,648.) Nov. 17.

18,758 (1920). Meister, Lucius, u. Brüning, Manufacture of pyridine bases. (146,869.) Nov. 17.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

British Dyestuffs Corp., Frank, Gibson, and Robinson, Manufacture of azo colouring-matters and an intermediate. 32,242. Nov. 15.

Davies, and Scottish Dyes, Ltd. Colouring-matters. 33,558. Nov. 27.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Barnett, and Imperial Trust. Production of cellulose esters. 31,684. Nov. 9.

Burgess, Ledward and Co., and Harrison. Treatment of cotton yarn. 32,508. Nov. 18.

Courrier. Producing paper pulp. 31,527. Nov. 8. (Fr., 11.11.19.)

Dreaper. Manufacture of viscose solutions. 31,465. Nov. 8.

Dreaper. Manufacture of artificial silk etc. 31,854. Nov. 10.

Dreaper. Manufacture and treatment of artificial filaments of organic origin. 32,706. Nov. 19.

Manoury. Obtaining cellulose and paper pulp from alfa grass etc. 32,123. Nov. 13.

Milne. Paper-pulp-refining engines. 33,360. Nov. 26.

Novosselsky. 32,005. See IX.

Roberts. Manufacture of articles from cellulose or its compounds. 33,427. Nov. 26.

COMPLETE SPECIFICATIONS ACCEPTED.

21,378 (1919). Drets and Noorden. Extraction of fibre from leaves etc. (153,413.) Nov. 17.

24,737 (1919). Muller. Manufacture of artificial threads, films, etc. from viscose. (153,444.) Nov. 17.

25,729 (1919). Bollmann. Removal of volatile solvents from materials treated therewith. (151,044.) Dec. 1.

1116 (1920). Hashimoto. Fibre, and process for obtaining same. (153,801.) Nov. 24.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Bowden and Bowden. Machines for bleaching, dyeing, etc. cloth. 32,509. Nov. 18.

Horsnell, and Simplex Patent Dyeing Machine Co. Dyeing, washing, etc. machines. 33,246. Nov. 25.

Marks (Duratex Co.). Coated fabric. 33,162. Nov. 24.

Nathan, Nathan, and Nathan. Treatment of textile fabrics. 32,657. Nov. 19.

Nelson. Apparatus for mercerising cotton. 32,651. Nov. 19.

Nelson. Mercerising cotton. 33,073. Nov. 24.

COMPLETE SPECIFICATION ACCEPTED.

23,199 (1919). Arent. Fireproofing and/or waterproofing treatment of materials. (132,813.) Dec. 1.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Jenkins. Apparatus for converting brine into salt. 32,178. Nov. 15.

Lundén and Thorsell. Production of nitrogen compounds. 32,060. Nov. 12. (Sweden, 3.12.19.)

Lundén and Thorsell. Production of pure nitrogen. 32,360-1. Nov. 16. (Sweden, 19.12.19.)

Ratner. Fixation of atmospheric nitrogen. 31,592. Nov. 8.

Roiboul. 32,711. See VIII.

COMPLETE SPECIFICATIONS ACCEPTED.

11,621 (1919). Catlett. Oxysalt compositions. (126,646.) Nov. 17.

17,084 (1919). Sherwin. Precipitation of aluminium hydrate. (153,352.) Nov. 17.

18,847 (1919). Henwood. Manufacture of nitric acid. (153,362.) Nov. 17.

19,391 (1919). Hobsbawn (Grigioni). Recovery of nitrate of soda from solutions. (153,649.) Nov. 24.

27,016 (1919). Hultman. Manufacture of chrome alum. (138,594.) Nov. 17.

30,832 (1919). Marks (West Coast Kalsomine Co.). Manufacture of iron compounds. (153,792.) Nov. 24.

1711 (1920). Sieurin. Production of aluminium oxide from the chloride. (153,500.) Nov. 17.

6009 (1920). Fabr. de Prod. Chim. de Thann et de Mulhouse. Manufacture of potassium sulphate and hydrochloric acid. (154,111.) Dec. 1.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Atkinson, Moreshead, and Stein and Atkinson. Glass furnaces. 32,703. Nov. 19.

Feldenheimer and Plowman. Treatment of clay. 31,505. Nov. 8.

Hancock. Saggers for firing pottery. 33,518. Nov. 27.

Roiboul. Manufacture of film silica, alumina, etc. 32,711. Nov. 19. (Fr., 16.9.20.)

Wade (Buckman and Pritchard). Manufacture of refractory material. 31,587. Nov. 8.

COMPLETE SPECIFICATION ACCEPTED.

20,339 (1920). Schidrowitz, Feldenheimer, and Plowman. Treatment of clay. (153,861.) Nov. 24.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Barrie and Chadwick. Aromatic hydrocarbon cement. 32,456. Nov. 17. (Australia, 27.5.18.)

Marks. Concrete. 31,969. Nov. 12.

Naaml. Vennoots. Netherland Colonial Trading Co. Composition for preserving wood etc. 32,501. Nov. 17. (Belg., 8.9.20.)

Novosselsky. Solutions for mineralising etc. wood, cardboard, etc. 32,005. Nov. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

14,855 (1919). Williams. Effecting colour transformation in wood. (153,619.) Nov. 24.

23,606 (1919). Ward. Manufacture of artificial stone. (153,433.) Nov. 17.

189 (1920). Smidth and Co. Building-material for concrete structures. (137,330.) Nov. 24.

10,436 (1920). Grubenholz-Imprägnierung Ges. Impregnation of wood. (141,728.) Nov. 24.

X.—MÉTALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Baker and Co. Alloys. 33,167. Nov. 24. (U.S., 20.1.20.)

Bowes. Soldering. 33,352. Nov. 25.

Bowes. Welding aluminium or its alloys. 33,353. Nov. 25.

British Scientific Instrument Research Assoc., Imperial Trust, Haigh, and Jackson. Manufacture of solder. 31,839. Nov. 10.

Brunskill. Preventing surface corrosion in aluminium alloys. 32,738. Nov. 19.

Dawson, and Ferranti, Ltd. Cast iron alloy. 33,290. Nov. 25.

Gibbons Bros., and Marle. Continuous annealing-furnaces. 32,767. Nov. 20.

Hess. Recovery of metal from chippings, residues, and ashes. 32,048. Nov. 12. (Ger., 3.4.18.)

Lemmon, Sulman, and Minerals Separation, Ltd. Recovery of gold from pyritic ores. 31,963. Nov. 11.
 MacLaren. Production of ferro-alloys. 32,198. Nov. 17.
 Ros. Oxidation of metals. 32,116. Nov. 13.
 Seiffert. Production of zinc dust. 32,028. Nov. 12. (Ger., 12.12.19.)
 Skudder. 33,571. See 1.

COMPLETE SPECIFICATIONS ACCEPTED.

7482 (1919). Bastian. Magnetic apparatus for use in heat-treatment of steel. (153,336.) Nov. 17.
 12,415 (1919). Goodwin and Cadenhead. Recovering vanadium from certain iron ores. (153,926.) Dec. 1.
 25,677 (1919). Sandberg and Humfrey. Heat treatment of steel. (153,756.) Nov. 21.
 3311 (1920). Edgley. Washing ores etc. (153,503.) Nov. 17.
 5519 (1920). Coles. Electrodeposition of alloys of copper and zinc. (154,108.) Dec. 1.
 5724 (1920). Hall, and Rolls-Royce, Ltd. Aluminium alloys. (153,514.) Nov. 17.
 5725 (1920). Hall, and Rolls-Royce, Ltd. Aluminium alloys. (153,823.) Nov. 24.
 7626 (1920). Elliott. Manufacture of wrought iron. (153,523.) Nov. 17.
 8727 (1920). Metallbank u. Metallurg. Ges. Bearing metals. (140,790.) Nov. 17.
 27,659 (1920). Goldschmidt A.-G. Increasing yield of chromium in the aluminothermic production of carbon-free ferrochromium or multiple alloys thereof from chrome-iron ore. (152,990.) Nov. 24.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Chloride Electric Storage Co. (Smith). Secondary battery plates or electrodes. 32,031. Nov. 12.
 Harrison (Dow Chemical Co.). Electrolytic cells. 32,208. Nov. 15.
 Masterman and Rogers. Electrolytic apparatus for preparing hypochlorite solutions. 32,039. Nov. 12.
 Pepper. Electric batteries. 33,562. Nov. 27. (U.S., 29.11.19.)
 Soc. Anon. Kummier & Matter. Manufacture of electrical resistance material. 31,804. Nov. 10. (Switz., 10.11.19.)
 Stewart. Electrodes for accumulators. 31,908. Nov. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

17,603 (1919). Universal Accumulators, Ltd., and Martis. Plates for accumulators. (153,935.) Dec. 1.
 20,034 (1919). Campbell. Electric furnaces. (153,951.) Dec. 1.
 20,688 (1919). Smalley. Heating elements for electric furnaces. (153,701.) Nov. 24.
 23,750 (1919). Hepburn, and Mather and Platt. Bi-polar electrode electrolyzers. (151,029.) Dec. 1.
 5549 (1920). Coles. See X.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Bates. Saponification. 32,007. Nov. 12.
 Clark and Co., and Tervet. 32,250. See II.
 Ellis. Thickening and bleaching oils. 33,405. Nov. 26.
 Jarrett. Manufacture of soap and soap powder. 32,000. Nov. 12.
 Mezger. Manufacture of grease. 32,925. Nov. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

17,356 (1919). Baker and Bonsall. Detergents. (153,634.) Nov. 24.
 19,286 (1919). Seobel. Producing solidification of oleaginous substances. (153,942.) Dec. 1.

19,739 (1919). Stephens (Sharples Specialty Co.). Extraction of lumpy and oily matters from wet sludges etc. (153,668.) Nov. 24.
 1129 (1920). Nordiske Fabr. De-No-Fa Akt. Deodorising and purifying fish oils. (140,372.) Dec. 1.

1974 (1920). Verein. Chem. Werke. See XVIII.
 17,464 (1920). Mayrhofer. Manufacture of a cleaning agent. (146,222.) Nov. 24.
 25,144 (1920). Davton Metal Products Co. Hydrogenation apparatus. (150,991.) Dec. 1.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Fitzgerald. Substitute for shellac etc. 32,878. Nov. 22.
 Marks (Stanley Insulating Co.). Producing and applying enamel coatings. 33,163. Nov. 24.
 Melamid. Manufacture of resinous substances. 33,435. Nov. 26. (Ger., 17.5.20.)
 Schou. Emulsions for painting and priming etc. 33,189. Nov. 24.

COMPLETE SPECIFICATIONS ACCEPTED.

31,550 (1919). Scudder and Pettigrew. Production of phenol-resin condensates. (153,796.) Nov. 24.
 1034 (1920). Birkby and Birkby. Production of phenolic aldehyde condensation products. (153,494.) Nov. 17.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Balke and Leysieffer. Production of plastic bodies resembling vulcanised rubber. 32,496. Nov. 17. (Ger., 19.3.19.)
 Earp and Wood. Press for continuously moulding, vulcanising, or curing rubber etc. 32,251. Nov. 15.
 White (Goodrich Co.). Vulcanisation of rubber. 31,955. Nov. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

13,992 (1919). Schidrowitz, Feldenheimer, and Plowman. Manufacture of rubber. (153,343.) Nov. 17.
 19,380 (1919). Young and Benner. Reclaiming rubber. (153,646.) Nov. 24.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Carmichael and Ockleston. Tanning. 31,494. Nov. 8.
 Chem. Fabr. Worms. Manufacture of tanning materials. 32,457 and 32,608. Nov. 17 and 18. (Ger., 18.11.19 and 20.8.17.)
 Lambeck. Making colouring of natural horn water-resisting. 32,891. Nov. 22. (Ger., 26.9.19.)
 Melamid. Manufacture of artificial tanning substances. 33,436. Nov. 26.

COMPLETE SPECIFICATIONS ACCEPTED.

537 (1920). Nakayama and Adachi. Utilising waste or scraps of leather. (154,095.) Dec. 1.
 3106 (1920). Wood. Puering or bating skins. (154,103.) Dec. 1.
 8417 (1920). Knudsen. Manufacture of fish-glue. (153,526.) Nov. 17.

XVI.—SOILS; FERTILISERS.

COMPLETE SPECIFICATIONS ACCEPTED.

23,730 (1919). Hyatt and Fellowes. Fertilisers and their manufacture. (153,434.) Nov. 17.

26,780 (1919). Baker and Shepherd. Fertiliser and insecticide. (154,057.) Dec. 1.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Cutler. Process of refining molasses. 31,540. Nov. 8.

Denington and Perry. 32,598-9. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Denington and Perry. Treating wood. 32,598. Nov. 18.

Denington and Perry. Apparatus for treating wood etc. to obtain fermentable sugars, furfural, acetic acid, etc. 32,599. Nov. 18.

Denington and Perry. 32,600-1. *See* 11.

Distillers Co., and Meyer. Process for denaturing alcohol. 31,589. Nov. 8.

COMPLETE SPECIFICATIONS ACCEPTED.

19,733 (1919). Akt. Dansk Gaeringsindustri, and Sak. Manufacture of yeast. (153,667.) Nov. 24.

19,830 (1919). Groll. Manufacture of fermentation preparations. (131,589.) Nov. 24.

1974 (1920). Verein. Chem. Werke. Manufacture of glycerol from sugar. (138,328.) Dec. 1.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Archer and Stevenson. Preserving and sterilising milk etc. 32,230. Nov. 15.

Callimachi. Treatment of potatoes etc. 32,602-3. Nov. 18.

Craig, and Spence and Sons. Purification of water. 32,644. Nov. 19.

Fitzgerald. Production of commercial products from blood. 32,741. Nov. 19.

Forget-me-not, Ltd., and Hutchinson. Ageing wheat and flour. 32,802. Nov. 20.

Hegney and Hegney. Sterilising milk. 31,603. Nov. 8.

COMPLETE SPECIFICATIONS ACCEPTED.

3245 (1919). Linden. Reducing the percentage of water in sewage, sludge, etc. (153,335.) Nov. 17.

20,298 (1919). Lendrich. Production of coffee substitutes. (153,971.) Dec. 1.

24,823 (1919). Hoyberg. Butter-making. (153,446.) Nov. 17.

7141 (1920). Manganoozone Soc. Anon. Sterilising and clarifying water. (140,077.) Nov. 24.

7381 (1920). Anhydrous Food Products Co. Drying fruits, vegetables, meats, etc. (140,102.) Nov. 24.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Bader, and Brit. Cellulose and Chemical Manuf. Co. Manufacture of alkyl compounds. 32,037. Nov. 12.

Denington and Perry. 32,598-9. *See* XVIII.

Green and Levinstein. Manufacture of a toxic product. 32,243. Nov. 15.

Kolshorn. 33,206-7. *See* III.

Marchand. Preparation of terpineol. 31,841. Nov. 10. (Holland, 10.11.19.)

I.—GENERAL; PLANT; MACHINERY.**PATENTS.**

Furnaces; Process and apparatus for operating —. G. and K. H. Siegwart, Asses. of R. Siegwart. E.P. 130,596, 25.7.19. Conv., 29.7.18.

AIR previously heated in a regenerator passes across the surface of a refractory tile or "gasifier" plate, and hydrocarbons and water (or steam) are supplied through separate jets approximately perpendicular to the gasifier plate. The plate may have a convexity, a concavity, or both upon its surface.

—B. M. V.

Heat-treating furnace. C. J. Kirk. E.P. 152,177, 25.8.19.

A LONG chamber is divided by a longitudinal partition into two compartments through which two sets of the objects to be heated are conveyed in opposite directions. Heat is transmitted from the hot goods leaving the chamber to the cold goods entering by means of air circulating through holes in the partition. The heating medium, e.g., hot products of combustion, is supplied from two separate combustion chambers situated near the middle of the length of the chamber, and passes through two separate sets of flues in the walls and roof surrounding the goods chamber, the two sets of flues leading towards opposite ends of the furnace. The hottest part of the furnace is at the middle, i.e., near the combustion chambers, whilst near the ends the incoming goods are heated partly by the heating flues and partly by air circulation from the hot goods leaving the furnace.—B. M. V.

Furnaces [; Recuperative] —. A. Smallwood. E.P. 153,042, 24.6.19. Addn. to 125,744 (J.), 1919, 489 A).

THE heated air for combustion is admitted to the combustible gas after the latter has left the primary combustion chamber, the admixture being made while the gases are in or leaving the intermediate heating flues. The air is preferably introduced into the heating flues by means of several ports distributed along their length.—B. M. V.

Shaft furnaces; Utilisation of the waste heat from —. A.-G. für Zinkindustrie vorm. Wilhelm Grillo. G.P. 321,524, 28.4.16.

TWO or more shafts are connected below by means of a combustion chamber or a reverberatory furnace, and each shaft is used in turn as a heat regenerator. For example air is preheated in one shaft (previously used as burning shaft) and passes to the combustion chamber, the hot gases from which heat the material in the second shaft. Alternately the gas may be preheated instead of the air, or by using four shafts, the air may be preheated in one pair and the gas in the other.

—W. J. W.

Drying apparatus. C. Whitfield. E.P. 152,712, 12.6.19.

THE goods to be dried are conveyed through a long chamber with perforated bottom under which radiators are placed. Air is circulated through the chamber and at the same time given a vibratory motion by means of a fan. There are two sets of radiators: primary ones, heated from an external source and preferably situated near the exit end of the chamber, and secondary ones through which the hot saturated air from the drying chamber is drawn by the fan, after which it passes to a vessel in which condensed moisture is deposited and is then fed back to the entrance end of the drying chamber. If desired, the secondary radiators may be in the roof of the chamber.

—B. M. V.

Drying apparatus. J. Killby and F. C. Allen. E.P. 152,922, 5.3.20.

A NUMBER of rotary drying chambers are arranged in a series so that the material lifted by the rotation of a chamber drops on to a shoot and is thus transferred from one chamber to another and finally discharged. Each chamber has a separate supply of drying gases, but these supplies may be derived from a single gas generator and the draught provided by a single suction fan.

—B. M. V.

Drying machine. J. L. Pierce. U.S.P. 1,356,469, 19.10.20. Appl., 11.6.19.

THE material to be dried is conveyed through a hot air chamber upon endless conveyors supported on ribs.—B. M. V.

Dryer; Chamber —. A. E. H. Beyer. G.P. 317,689, 3.5.14.

THE drying chamber is divided into separate compartments and hot air is led in both at the top and through the floor. The end compartments are connected below the floor by conduits for conveying hot air from the one to the other, or for separating moisture from the air; the conduits are connected with each compartment by valves operated from the top, and are also connected with the apparatus in which the moist vapour is condensed.—L. A. C.

Mercury or other fluid having a high boiling point; Boilers particularly intended for vaporising —. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 152,785, 23.7.19.

THE boiler consists of a number of separate sections assembled within a casing, each section comprising a pair of vertical plates slightly spaced apart to form a container for the mercury. The sections are provided with external vertical ridges on their faces, formed by pressing the plates, so that when assembled a tortuous passage alternately upward and downward is formed for the heating gases. The interior of the sections is provided with vertical partitions forming similar passages for the mercury. The passages are so arranged that when the mercury enters the section it travels upwards in the same direction as the hot gas, but in its final movement it travels in the opposite direction to that of the hot gas, the mercury making three passes and the hot gas two passes in each section. The sections are supported so as to provide for expansion, and each is provided with preheating passages at the outer edges. The mercury vapour is used to drive a turbine or other prime mover, the exhaust from which is used to generate steam, and the hot waste gases are used for superheating steam.

—W. F. F.

Refrigerating; Method of and apparatus for —. B. Thoens. E.P. 152,898, 21.12.19.

IN a method of refrigerating by evaporation of a volatile fluid such as ammonia from its solution, a part of the cooled solution is used to absorb the vapour removed from another part by evaporation, the second part being then used for refrigerating. Part of the cool refrigerant from the evaporating tank is circulated through a closed circuit which includes the absorbing tank but not the refrigerator, and another part is circulated through a separate closed circuit which includes the refrigerator but not the absorbing tank.—W. F. F.

Refrigerating machine. R. Plersch and H. Meidinger. G.P. 322,796, 28.2.19.

THE vapours of the refrigerating agent coming from the evaporator are condensed by a jet compressor contained within the condensing apparatus. The refrigerating liquid, cooled by means of cold vapours

arising from the evaporator is employed as working fluid in the jet compressor, and is kept in circulation by means of a pump.—J. S. G. T.

Grinding ores, minerals, stones and the like; Machines for — J. R. Broadley. E.P. 152,724, 8.7.19. Addn. to 116,583 (J., 1918, 453A).

By rearranging the parts of the screening device the passage for the return of oversize material to the mill may be formed as a single trough or tube of involute shape. Trunnions may be used to support the mill instead of tyres and rollers.—B. M. V.

Pulverising apparatus. J. E. Kennedy. U.S.P. 1,356,292, 19.10.20. Appl., 2.2.18.

CRUSHING rollers mounted on vertical spindles which revolve around a central vertical axis move in contact with a fixed grinding ring. Material is fed between the ring and rollers from below, and a central fan is provided for directing air under pressure between the ring and rollers from below.

—W. F. F.

Evaporator and method of operating such evaporator. G. H. Benjamin. U.S.P. 1,355,935, 19.10.20. Appl., 23.2.18.

LIQUID is evaporated in a chamber at a controlled temperature by means of steam coils, and the vapour passes into a superheating chamber, where it is heated to a controlled temperature by an electric heater.—W. F. F.

Condensing [evaporating] apparatus. I. S. Merrell, Assr. to Merrell-Soule Co. U.S.P. 1,356,082, 19.10.20. Appl., 26.12.16.

AN evaporating chamber and its cover are both carried by the same framework, and are movable relatively to one another. A rotary heater is provided in the evaporating chamber, driven by a shaft passing through the cover, the shaft being separable into two sections when the cover is lifted.—W. F. F.

Evaporators; Means for ensuring the formation of a thin film of the liquid under treatment on the inner walls of the tubes of vertical tube — A. G. der Maschinenfabr. Escher, Wyss und Co. G.P. 321,937, 22.1.19.

THE top of each tube is opened out to form a curved surface of such a shape that the descending liquid tends to flow along the inner wall of the tube, leaving the central portion empty. The tops of the tubes are at progressively lower levels the greater their distance from the liquid inlet.—L. A. C.

Container for alkaline substances. G. W. Howlett, Assr. to The Research Laboratories Co. U.S.P. 1,355,976, 19.10.20. Appl., 10.7.19.

AN alkali-proof coating composition for fibre receptacles consists of a cellulose ester dissolved in a solvent and mixed with a non-solvent and with a material to render the coating less brittle.

—B. M. V.

Distillation or the like; Apparatus for — V. L. Emerson. U.S.P. 1,356,057, 19.10.20. Appl., 11.5.20.

A FURNACE for heating a tubular evaporator is arranged so that the combustion products pass downwards into a pit and thence to the bottom of the stack. The pit is constructed so that when filled with liquid the passage leading from the furnace is closed.—W. F. F.

Distillation; Process of — D. L. Newton. U.S.P. 1,356,878, 26.10.20. Appl., 11.9.18.

A LIQUID containing a volatile substance is passed in the form of a film through a distilling chamber at ordinary temperature, and subjected to a partial vacuum to distil off the volatile substance.

—W. F. F.

Vapour in a natural gas; Method of condensing a — J. T. Duffy. U.S.P. 1,356,196, 19.10.20. Appl., 27.5.18. Renewed 6.5.20.

THE gas is simultaneously cooled and subjected to the action of an alternating brush discharge, thereby producing a nucleus around which the vapour will condense.—L. A. C.

Separating apparatus. E. L. Marshall. U.S.P. 1,356,384, 19.10.20. Appl., 11.8.19.

MATERIAL to be separated is fed from a hopper, and meets a horizontal blast of air. The heavier particles fall into a conduit, from which they pass out of the apparatus, while the lighter particles are carried through an opening between vertical plates, one of which is adjustable to vary the opening. The heavier particles fall into a conduit and are separated into two grades in passing over a perforated floor, the coarser grade being returned by a conveyor to the hopper. The air carrying the lighter particles then passes into a larger chamber, where the particles are kept in suspension by suction and the lightest particles are drawn off. The heavier particles are partly deposited on a sloping floor and are withdrawn through an outlet, while the air carrying the remainder of the material passes to another chamber, in which the heavier particles are again separated, and are directed by guide plates to the sloping floor, while the air containing the finest particles in suspension passes out at the top of the casing.—W. F. F.

Electrical precipitation of suspended matter in gaseous and fluid bodies; Apparatus for — Removing suspended particles from fluid or gaseous bodies. Producing electrical precipitation of particles from fluid or gaseous streams. A. F. Nesbit, Assr. to International Precipitation Co. U.S.P. (A) 1,356,462, 19.10.20, (B) 1,357,201, and (C) 1,357,202, 26.10.20. Appl., (A, B) 17.11.14, (C) 16.9.15.

(A) AN electrode frame is arranged between spaced plate-like receiving electrodes forming a gas passage. A series of parallel, flexible discharge members extending longitudinally through the passage are held rigidly by the frame. (B) The discharge system of opposing electrode systems comprises a number of wires arranged spirally in the direction of length of the system, each wire having its axis out of the axis of symmetry of the opposing electrode system, whereby an unsymmetrical field is produced in the various cross-sections of the system, through which the fluid stream tends to flow spirally. (C) The discharge system of opposing electrode systems comprises a frame carrying rigidly a number of electrode elements arranged parallel to one another and to one side of the frame.

—J. S. G. T.

Oxidation process; Catalytic acceleration of — C. S. Piggot. U.S.P. 1,357,000, 26.10.20. Appl., 3.1.20.

THE material to be oxidised is heated with a gas containing oxygen in the presence of a catalyst consisting of an alloy of metals precipitated by hydrogen sulphide in alkaline solution.—L. A. C.

Heat exchanger for condensation of petroleum or tar vapours etc. A. J. Irinyi. G.P. 322,745, 22.3.14.

THE vapour to be condensed and the cooling liquid are passed through series of adjacent channels, wide at one end and narrow at the other, formed by suitably corrugated partitions, consecutive channels tapering in opposite directions. The vapour and the cooling liquid circulate at right angles to the length of the channels and from the wide to the narrow ends, so that the velocity acquired at the narrow end of one channel is transformed into a

whirling motion when the fluid enters the wide end of the next. The channels through which the vapour passes may be provided with discharge outlets for condensed liquid at their lowest points.

J. H. L.

Filters; Operation of drum —. G. Polysius. G.P. 324,730, 27.6.19.

The filter fabric is fastened to the drum by windings of wire or cord, consecutive turns being disposed a short distance apart. The filter cake is removed from the rotating drum by means of jets of liquid, and as a result of the uneven surface produced by the wire or cord it comes off easily in narrow strips, so that jets operating under a lower pressure than usual can be employed, and wear of the filtering fabric is consequently diminished.

—J. S. G. T.

Filter drum. H. Hencke. G.P. 324,797, 3.8.18.

The filter cloth is secured to the circumference of the filter drum by means of pressure bars or rollers etc.—J. S. G. T.

Hoo canal. Strata associated with coal. I. F. S. Sinnatt and M. Barash. Bull. 6, Lancs. and Cheshire Coal Res. Assoc., 1920, 15 pp.

The term Hoo canal is largely used in Lancashire for canals containing a high percentage of ash to distinguish them from low-grade shales. Seams varying in thickness from a few inches to several feet occur in the Lancashire coalfield. The average composition of the specimen (from Hindley) examined was: moisture 2.10%, volatile organic matter 31.60%, coke 66.30%, fixed carbon 39.78%, ash 24.42%; C 60.74%, H 4.23%, N 1.30%, S 1.23%, and O 8.08%. The calorific value was 11,000 B.Th.U. per lb. (14,700 B.Th.U. on an ash-free basis). Extraction with pyridine yielded 12.7% of extract compared with 29.4% of extract from the coal associated with the canal (both figures calcu-

lated to an ash-free basis). The ash would seem to be an inherent constituent of the canal substance, since no improvement in composition could be effected by crushing and washing the material. Hoo canal can be pulverised approximately much more easily than Arley coal, and might be suitable for powdered fuel firing. Similar material from the Burnley area averaged 15.5% of ash and 19.0% of volatile organic matter; from the Bickershaw area 32.1% of ash and 28.3% of volatile organic matter; and from the Garswood area 10.1% of ash and 48.1% of volatile organic matter. Carbonisation of the Hindley canal at 920° C. yielded 9870 cb. ft. of gas per ton, or corrected to 16 c.p. 9210 cb. ft. at n.t.p. The c.p. was 15.0 and the calorific value 521 B.Th.U. per cb. ft. The coke yield was 68.9% and the tar yield 8.0 gals. per ton (4.1% by weight). The tar had sp. gr. 1.119 at 20° C. and yielded the following fractions: Up to 170° C., 6.8%; 170°–230° C., 15.5%; 230°–270° C., 8.95%; 270°–330° C., 22.9% and 45.0% of a brittle pitch. There is a much smaller yield of naphthalene and a much larger yield of anthracene from canal tar than from coal tar.—A. G.

Sulphur in coal; Reactions of — in the coking process. A. R. Powell. J. Ind. Eng. Chem., 1920, 12, 1069–1076.

In the coking of coal pyrites and marcasite are decomposed completely into ferrous sulphide, pyrrhotite, and hydrogen sulphide, the reaction beginning at 300° C., usually reaching its maximum between 400° and 500° C., and being complete at 600° C. Sulphates are reduced to sulphides, the reaction being complete at 500° C. Primary decomposition of organic sulphur compounds to form hydrogen sulphide is most active below 500° C.; about a half of the organic sulphur is thus eventually decomposed. A small portion of the organic sulphur reacts at the lower temperatures of the process to form volatile organic sulphur compounds, most of which will be found in the tar. The remainder of the organic sulphur undergoes a pronounced change between 400° and 500° C. The total amount of sulphur in the coal is the most important factor affecting the sulphur content of the coke. The secondary reaction between the sulphur in the red-hot coke and the hydrogen in the by-product gases passing through it cause a more pronounced reduction than the primary reactions would indicate (*cf. infra*). Coke has been found to contain a magnetic iron sulphide, probably pyrrhotite.—C. A. M.

Coke; Desulphurising action of hydrogen on —. A. R. Powell. J. Ind. Eng. Chem., 1920, 12, 1077–1081.

HYDROGEN passed through coke for 3 hrs. at 1000° C. removes most of the sulphur without affecting the character of the coke. The effect of passing hydrogen through coal in the process of coking is to modify three of the sulphur reactions. The pyrites decomposes at a lower temperature (500° C.) without, however, affecting the final results. The decomposition of organic sulphur to form hydrogen sulphide is but little affected below 500° C., but is very greatly increased between 500° and 1000° C. This increased decomposition is the cause of the desulphurising action of hydrogen. A larger amount of the sulphide is converted into a "carbon-sulphur" combination. Gaseous mixtures containing hydrogen, such as coke-oven gas, although effective, are much slower in their action and would probably never effect so complete a removal of sulphur as hydrogen. The circulation of by-product gas through the coking mass may, however, be of commercial value. The desulphurising process is not affected by the original state of subdivision of the coal.—C. A. M.

Coke-ovens; Regulation of gas pressure in —. A. Thau. Glückauf, 1920, 56, 901—906, 925—930.

No coke-oven being a gas-tight chamber, pressure differences between the chamber, the heating flues, and the outside air lead to leakages. With a positive pressure in the oven the consequences are loss of gas, and carbon deposits in the heating flues. With a negative pressure partial combustion of the gas takes place in the oven and the resulting rise in temperature damages the exit pipes and leads to decreased yields of tar, benzol, and ammonia, and to poor gas. For ordinary working a slight positive pressure should be maintained. This principle applies to all retort practice, with or without steam, and whether gas or coke is the main desideratum. The idea that the yields of by-products can be increased by applying suction is erroneous. In many coking plants the pressure is regulated by the aid of a control flame allowed to burn on a branch pipe from the gas main. Detailed pressure measurements taken on a Koppers oven, with corresponding gas analyses, are given to show the defects of this method. The pressure is lowest at the two end doors of the oven, somewhat higher along the top, and much higher in the gas-main. Hence suction on the oven and a bad gas composition can co-exist with pressure on the gas-main and the control flame burning. The device of allowing control flames to burn at the observation holes of several oven doors is preferred. Attempts to devise an automatic control operating from a manometer to the blowers have met with great difficulty owing to the tar vapour and temperature of the gas. To render such control practicable the difference of pressure between the ovens and the point in the main connected with the manometer, which varies for each plant and may vary in the same plant with the moisture content of the coal and the deposition of carbon in the pipes, must be accurately known. A description of a membrane micromanometer and of the mechanical details of automatically controlled blowers is given.—C. I.

Flue gases derived from the combustion of coal; Graphic representation of the analysis of —. F. Schulte. Glückauf, 1920, 56, 532—536.

The system of triangular coordinates introduced by Ostwald (J., 1919, 492A), whereby the characteristics of combustion are represented by points associated with a right-angled triangle is used to represent the results of combustion of coke, anthracite, lean coal, fat coal, gas coal, and coal very rich in volatile combustible matter. Analyses of typical samples of these various coals are given and are accompanied by triangular diagrams appropriate to the respective cases. The method of construction of the diagrams is explained, and data are provided for their construction in the case of any of the typical coals enumerated. The application of the diagrams to the determination of the characteristics of the combustion, utilising the results afforded by analysis of the flue gases, is briefly explained. The correctness or otherwise of the analysis is thus readily ascertained; likewise the completeness or otherwise of the combustion and whether excess of air is being used or not.—J. S. G. T.

Flames; Silent aerated —. H. Davies. Yorks. Junior Gas Assoc. Gas World, 1920, 73, 387—388, 407—409.

The noise of an aerated flame is not necessarily due to imperfect mixing of gas and air, nor to the presence of eddies in the current of the mixture. A flame produced at the orifice of a single tube by the combustion of a homogeneous gas-air mixture is noisy if a critical consumption, depending upon the length and bore of the tube, is exceeded. The consumption rises to a maximum corresponding to a particular composition of the gas-air mixture.

With this mixture consumption increases as length of the tube increases until a critical length is reached, after which the consumption is constant. When lengths equal to, or greater than, the critical lengths of tubes of different diameter are compared, the consumptions producing just silent "silent steady" flames are nearly proportional to the internal diameters or perimeters of the tubes. The author explains these observations by suggesting that differences in frictional resistance with different lengths of tubes and with tubes of different diameters, cause differential velocities of the gas stream. A certain differential value is necessary for a steady flame.—W. P.

Radiation in explosions of hydrogen and air. W. T. David. Proc. Roy. Soc., 1920, A 98, 183—198.

THE radiation phenomena in hydrogen mixtures are, in general, similar to those in coal-gas mixtures (cf. J., 1919, 707A; 1920, 218A). The maximum rate of emission, however, occurs approximately at the point of maximum temperature, and not during the explosion period, as in the case of coal-gas mixtures. Further, the proportion of the heat of combustion lost by radiation during explosion and subsequent cooling decreases with the mixture strength (and hence with the maximum temperature developed) much more rapidly in the hydrogen mixtures than in the coal-gas mixtures. The 2.8μ emission band of steam ceases to be emitted when the temperature has fallen to about 1000° abs., and the results are taken to indicate that the vibratory degrees of freedom of the steam molecules corresponding to radiation of 2.8μ share the heat energy of the molecules only above 1000° abs.; this may account for the rapid increase of specific heat in this region.

—J. R. P.

Gases; Behaviour of explosive mixtures of — at low pressures. A. Stavenhagen and E. Schuchard. Z. angew. Chem., 1920, 33, 286—287.

EXPLOSIVE mixtures of gases no longer ignite when the pressure falls below a definite limit. The intensity of the explosion decreases with the fall in the pressure, and below the critical pressure slow combination takes place without flame. The critical pressure stands in relationship to the nature of the gas, the proportions of the mixture, the moisture, and the initial impulse. The possibility of a second explosion in a closed space is greater in proportion to the smallness of the pressure developed by the first explosion, or to the reduction in pressure following the first explosion. (Cf. J.C.S., Jan., 1921.)

—C. A. M.

Hydrocarbons; Dispersion of the refraction of —. E. Darmon. Comptes rend., 1920, 171, 952—955.

THE specific dispersion, $\Delta n/d$, where Δn is the difference in the refractive indices for $H\alpha$ and $H\gamma$, and d is the density at the same temperature, is apparently constant to within one or two units for each class of hydrocarbons, and may be used to distinguish between saturated, unsaturated, and benzenoid hydrocarbons. In the case of unsaturated hydrocarbons the value of the ratio increases with the number of double bonds present. The following values are given: Saturated aliphatic hydrocarbons and saturated cyclic hydrocarbons (cyclohexane series), 155; unsaturated cyclic and unsaturated aliphatic hydrocarbons with one double bond, 190; unsaturated aliphatic hydrocarbons with two double bonds, 225—230; benzenoid hydrocarbons, 300.—W. G.

Oils; Apparatus for determining the fluidity of — at low temperatures. Giorn. Chim. Ind. Appl., 1920, 2, 388—390.

THE oil is introduced into a calibrated U-tube 6 mm. in diam. up to the zero point of a scale

graduated in mm. The tube is chilled in a bath of the required temperature, and a pressure of 50 mm. of water is exerted in one of the two limbs of the tube. The amount of displacement of the oil in a given time, as measured on the scale, affords an index of its fluidity. A special chamber to receive a number of such tubes is described, in which the low temperature is produced by the expansion of liquid carbon dioxide from a cylinder attached to the chamber by means of a valved tube. The pressure applied to the tubes is regulated by a water manometer, and the chamber is provided with an observation window.—C. A. M.

Lubricants and emulsification. V. R. Abrams, C. H. Osmond, and T. G. Delbridge. Amer. Soc. Testing Materials. Petrol. Mag., 1920, 10, 126—152.

STEAM is injected into a 20 c.c. sample of oil contained in a test-tube. The emulsion is maintained at constant temperature by means of a water jacket at a definite temperature. The tube is then transferred to a separating bath maintained at 200°—203° F. (93°—95° C.), and the time taken for the oil to separate completely, or if complete separation has not taken place in 20 mins. the volume of separated oil, is determined. If the emulsification is commenced at 67° F. (19.5° C.) it is complete in 4—7 mins., by which time the temperature will have reached 190°—195° F. (88°—90.5° C.).—A. E. D.

Ammonium sulphate. Raschig. See VII.

Waste roofing felt. Hawley and Kress. See IX.

PATENTS.

Coke oven. A Roberts, Assr. to American Coke and Chemical Co. U.S.P. 1,356,788, 26.10.20. Appl., 15.9.16.

A **COKE-OVEN** heating wall provided with internal flues is constructed of blocks laid in courses, each block having three of its faces, perpendicular to the wall surface, made plain, and the fourth surface notched, the notches extending across the courses. The ends of the blocks are in alinement vertically, and spacing blocks are placed between the ends of consecutive courses of blocks so that the central portions of the blocks are in communication with the recesses formed by the notches.—W. F. F.

Gas retorts; Vertical —. Soc. Anon. d'Ougrée Marihay. E.P. 135,214, 15.11.19. Conv., 28.9.16.

COAL is supplied continuously to the top of vertical retorts of oblong cross-section, the side walls of which are heated by adjacent combustion chambers, while the end walls are not heated. The pasty layer of coal is of V-cross-section and gas-discharge openings are arranged in the unheated walls along or parallel to the V outline to prevent overheating of the products. The gas-collecting compartments are moderately heated either by the combustion air from the lower parts of the regenerator or by the fire gases which have passed along the retort walls or by special burners.—W. F. F.

Retorts for the distillation of carbonaceous materials; Heating of vertical —. J. West, W. Wild, and West's Gas Improvement Co. E.P. 153,139, 30.8.19.

VERTICAL retorts for coal distillation are heated by external combustion chambers, and to equalise the temperature in these chambers each is provided with two secondary air inlets, one adjacent to the flame orifice at which a limited amount of air is admitted, and the other midway between the ends of the combustion chamber to admit air to complete the combustion.—W. F. F.

Water-gas; Manufacture of —. A. Meade. E.P. 153,051, 28.6.19.

The supply of steam to the generator is automatically controlled in accordance with the pressure in the gas-exit pipe, and therefore with the temperature in the generator, by means of a flexible membrane stiffened at the centre. One side of this membrane is exposed to the pressure of the gas, and the movement of the central stiffening piece controls the steam valve by means of a valve rod and link motion.—C. I.

Lignite; Pre-treatment of friable — for gasification in by-product gas producers. Deutsche Erdöl A.-G., F. Seidensehnur, and C. Koettnitz. G.P. 323,588, 29.11.16.

The raw lignite is mixed with sulphates and formed into lumps. 1000 kg. of lignite, mixed with 250 kg. of concentrated magnesium sulphate solution, may be dried in a rotary drum and the dried balls fed into a generator and gasified; the sulphur of the sulphate is evolved as hydrogen sulphide, from which sulphur is obtained by interaction with sulphur dioxide. If calcium sulphate is employed it is reduced to sulphide, which is extracted with water and decomposed with carbon dioxide, and from the hydrogen sulphide evolved sulphur is obtained by a known method.—J. H. L.

Gas from blast furnaces, gas generating plants and the like; Apparatus for washing and drying —. E. F. Hickman. E.P. 153,053, 17.7.19.

Gas is passed downwards through a column fitted with water sprays at the top and also with further water-supply connexions at different heights. The column contains a number of turbines driven by the falling water, with interposed distributors for the gas and water. The washed gas is dried by a turbine rotated by the gas pressure and is finally passed through an annular perforated plate or filter.—C. I.

Tar-extractors and scrubbers for gas. J. F. Wells. E.P. 153,109, 7.8.19.

A **SERIES** of chambers is arranged one above the other in vertical column, each chamber being provided with a central gas inlet and outlet and a disc-shaped horizontal baffle fitted with vanes and revolving on a central vertical shaft. A water jet is introduced above each baffle, and the water and tar are drawn off through outlets at the periphery. The gas undergoes a final cleaning in an annular chamber packed with sawdust at the top of the column.—C. I.

Inert gases [products of combustion]; Process and apparatus for producing —. J. J. Shea, Assr. to The Hartford Rubber Works Co. U.S.P. 1,356,888, 26.10.20. Appl., 5.4.20.

A **COMBUSTIBLE** gas mixed with its exact equivalent of air is burnt on refractory surfaces, and the gases of combustion are dried.—C. I.

Lubricants; Wire-drawing —. A. S. Cache-maille. From Westinghouse Lamp Co. E.P. 137,329, 2.1.20.

FINELY divided graphite is held in suspension by a gelatinous, non-adhesive vegetable medium, e.g., agar-agar. The product is specially suitable for use as a lubricant for hot wire drawing, e.g., of tungsten.—A. E. D.

Petroleum or other hydrocarbons, or mixtures of volatile liquids; Apparatus for continuous distillation and fractionation of —. H. L. Allen. E.P. 152,791, 21.7.19.

An improvement of the method and apparatus described in Fr. Pat. 481,131 of 1916 (J., 1917, 127). The vapours from the stills pass through pre-

heaters, which are constructed in three superimposed compartments. Crude oil is fed into the lowest compartment and thence passes through tubes extending up through the middle compartment and discharging into the upper compartment. The intermediate compartment is heated by the vapours from the stills. From each pre-heater the crude oil flows in series to the next, and from each upper compartment of the pre-heater vapour passes into a fractionating device consisting of atmospheric condensers connected in cascade fashion. It is claimed that results superior to those provided by existing dephlegmation methods are obtained.

—A. E. D.

Petroleum, tar, and the like industry; Preheater for use in the chemical industry, especially for use in the —. L. Steinschneider, Assr. to The Chemical Foundation, Inc. U.S.P. 1,337,287, 20.4.20. Appl. 3.11.14.

A PREHEATER for use in the distillation of petroleum, tar, and the like consists of an upright vessel to which the liquid to be preheated is supplied and within which is a system of horizontal tubes through which the vapours evolved when the liquid is distilled are passed. The system of tubes is enclosed in a jacket of smaller cross-sectional area than the upright vessel, and means are provided for controlling the circulation of the liquid being preheated through and around the jacket.

Petroleum; Apparatus for cracking —. H. W. Jones, Assr. to The Kansas City Gasoline Co. U.S.P. 1,356,208, 19.10.20. Appl. 27.5.16.

OIL is preheated in a low-pressure boiler and passed continuously through a number of separate, subdivided units, arranged in parallel, wherein it is cracked at high temperature and pressure. The cracked product passes from each unit into a common receiver and thence into condensers.

—L. A. C.

[Paraffin] wax; Method of extracting —. H. M. Nichols, Assr. to The Atlantic Refining Co. U.S.P. 1,356,550, 26.10.20. Appl. 7.3.19.

A COOLED wax-bearing liquid, e.g., a paraffin distillate, is pressed into contact with one side of a filtering medium, the opposite side of which is in free contact with air maintained at a temperature below that of the liquid. The wax collects upon the filter medium and the liquid passes through and is collected. (Cf. U.S.P. 1,302,832; J., 1919, 493 A.)

—L. A. C.

Low-boiling hydrocarbons, e.g., petroleum spirit; Manufacture of — from natural gas or other purified gases. Apparate-Vertriebs-Ges.m.b.H. G.P. 307,624, 26.8.16.

THE gas is alternately compressed and allowed to expand, and as it expands it is scrubbed with a cooled atomised wash liquor.—L. A. C.

Montan wax; Production of — from lignite. A. Riebeck'sche Montanwerke A.-G. G.P. 325,165, 25.1.19.

IN a process of extracting lignite containing not more than 25% of moisture, with a mixture of benzene and a second solvent, the second solvent employed is a mixture of alcohol (in particular methyl alcohol) and acetone, preferably acetone oil. The yield of bitumen extracted is much greater than when benzene alone is used.—J. H. L.

Fuel suitable for a substitute for spirit and the like, and process for producing the same. W. Hänig. G.P. 325,711, 20.9.19.

THE fuel consists of hexamethylenetetramine, in the form of powder or compressed tablets or flakes, to which may be added other substances which facili-

tate combustion or ignition. Porous or absorbent materials, such as wicks, kieselguhr, etc., may be impregnated with solutions of hexamethylene-tetramine.—J. H. L.

Filtering agents [fuller's earth from treatment of oils]; Revivification of —. C. F. Kennedy, Assr. to The Atlantic Refining Co. U.S.P. 1,356,631, 26.10.20. Appl., 11.8.19.

THE material is treated with an aqueous soap solution.—L. A. C.

"Norit"; Adsorbent power of — compared with that of blood charcoal. H. R. Kruyt and C. F. van Duin. Rec. Trav. Chim., 1920, 39, 679—684.

BLOOM charcoal, purified with acid, has a stronger adsorbent power for hydrogen and hydroxyl ions, phenol, bromine, and the sulphoeinamic ion than either commercial norit or norit purified by boiling first with dilute hydrochloric acid and then with water.—W. G.

Tungsten pigments. Gardner and Reilly. See XIII.

PATENTS.

Wood, woody fibre and similar carbonaceous substances; Destructive distillation of —. P. Poore. E.P. 152,741, 15.7.19.

WOOD, woody fibre, or the like is distilled in a retort heated externally, and after the temperature has been raised above 100° C. steam at a temperature of 180°—270° C. is admitted. A high yield of acetic acid, wood naphtha, etc., is obtained.—W. F. F.

Carbonisation of wood; Process and apparatus for the — in ovens. M. Fritz. G.P. 321,376, 30.6.14.

THE gases and vapours are withdrawn from the vertical carbonising chamber through outlets distributed over the whole height of the charge and are sucked in the direction of that end of the oven at which the carbonisation of the charge commences. Condensation in the uncarbonised parts

of the charge and the need for the re-vaporisation of the condensed products are in this way avoided.

—G. F. M.

Carbonisation of cellulose, peat, etc., by treatment under pressure and heat in presence of liquids. J. Billwiller. G.P. 323,595, 6.3.17.

Viscous liquids, such as tar oils, petroleum, mercury, salt solutions, or fused materials, are employed, and the temperature is raised to over 360° C. according to requirements. Homogeneous anthracitic products are obtained which are specially suitable for the manufacture of electrodes. As by-products, considerable quantities of tar and compressed gases (hydrogen, carbon dioxide, methane, etc.) are obtained.—J. H. L.

Kiln; Two-chambered shaft — for low temperature carbonisation of bituminous substances. Torfentgasung-Stauber G.m.b.H. G.P. 321,577, 29.1.19.

The dividing wall between the two chambers does not reach the top, so that a gas-collecting space common to the two chambers is formed into which a steam jet and the gas exit bells are built. The gas is removed from the apparatus before the temperature of decomposition of ammonia is reached.

—C. L.

Incandescence bodies consisting of a conductor embedded in rare earths; Preparation of —. J. F. Rahtjen. G.P. 321,304, 30.4.14. Addn. to 308,036 (J., 1918, 728 A).

A CONDUCTING wire is wound helically round a core of textile fibres and then covered with fabric and impregnated as in the main patent (*loc. cit.*) The wire cuts into the fibrous core and the latter then insulates the individual turns of the coil from one another and prevents short-circuiting. After burning off, the incandescence body is strengthened by heating for a short time by the electric current in a neutral atmosphere such as hydrogen.—W. J. W.

Incandescence cathode for use in [cathode ray] discharge tubes employing a high vacuum. Ges. für drahtlose Telegraphie m.b.M. G.P. 325,002, 13.12.17.

THE specific electronic emission of a tungsten cathode is increased by subjecting it to the action of hydrogen before producing the vacuum in the discharge tube. In this manner, employing a heating current of 2.1 ampères, the electronic emission is increased from 0.5 milliamp. to 150 milliamp.

III.—TAR AND TAR PRODUCTS.

Naphthalenesulphonic acids; Sparingly soluble salts of certain —. J. A. Ambler. J. Ind. Eng. Chem., 1920, 12, 1081—1085.

THE α - and β -naphthylamine salts of naphthalene β -, 1.5-, 1.6-, 2.6-, and 2.7-sulphonic acids have been prepared in crystalline condition, and their physical and chemical characters are described. All of them dissolve with difficulty in water, the 1.5 salt being the least soluble, and all are readily hydrolysed when boiled with water. Ferrous naphthalene- β -sulphonate, $\text{Fe}(\text{C}_{10}\text{H}_7\text{SO}_3)_2 \cdot 6\text{H}_2\text{O}$, crystallises in colourless glistening plates. It dissolves with difficulty in cold water, but is readily soluble in hot water. When heated at 150°—160° C. it loses its water of crystallisation. It is characterised by its unusually low refractive index (D)— n_D^{20} 1.500. (*Cf.* J.C.S., Jan., 1921.)—C. A. M.

Naphthalenesulphonic acids; Method for the detection of certain —. J. A. Ambler and E. T. Wherry. J. Ind. Eng. Chem., 1920, 12, 1085—1087.

FOR detecting the various sulphonic acids formed in the sulphonation of naphthalene the following tests are applied to a solution of the sodium salts of the acids. The presence of naphthalene- β -sulphonic acid is shown by precipitation of glistening crystals of the ferrous salt; these separate only after some time from dilute solutions. From the boiling filtrate a granular precipitate of α -naphthylamine naphthalene-1.5-disulphonate produced by means of a freshly-prepared solution of α -naphthylamine hydrochloride indicates the corresponding acid. The liquid is filtered hot, the excess of the base removed by titration with sodium hydroxide, and the solution cooled and filtered. The filtrate is heated to boiling and treated with a large excess of boiling β -naphthylamine hydrochloride, which will form a white precipitate of β -naphthylamine naphthalene-2.6-disulphonate if the corresponding acid is present. The solution is filtered rapidly while hot, and the filtrate cooled, and left for at least 1 hr. Should a jelly be formed the liquid is diluted, boiled, and again cooled. The salts are then separated, dried *in vacuo* at 100° C., and a small amount boiled with acetone, the liquid filtered and the filtrate cooled. The separation of crystals of β -naphthylamine naphthalene- α -sulphonate indicates the presence of α -sulphonic acid. The optical behaviour of the salts (see preceding abstract and J.C.S., Jan., 1921) is utilised to detect the presence of naphthalene-2.7- and 1.6-disulphonic acids.

IV.—COLOURING MATTERS AND DYES.

Extract of old fustic (morine) and quercitron extract (quercitrin); Differentiation of —. E. Justin-Mueller. Bull. Soc. Chim., 1920, 27, 844—846.

THESE two extracts appear quite different under the microscope, that of quercitron showing more or less agglomerated granules, while that of old fustic shows well-defined crystals. If a trace of either extract (dry or concentrated liquid) is dissolved in sulphuric acid (66° B., sp. gr. 1.84) and then diluted with water, the extract of old fustic remains bright orange-yellow, while that of quercitron is decolorised.—W. G.

PATENTS.

Azo dyestuffs; Manufacture of — and intermediate products therefor. O. Imray. From Soc. of Chem. Ind. in Basle. E.P. 149,553, 12.5.19.

NAPHTHALENEDISULPHOCARBOXYLIC acids containing a sulpho group in the 1-position are nitrated, the resulting 8-nitro-derivatives are reduced, the amino group replaced by a hydroxyl group, and the products subjected to partial fusion with alkali. The 1,8-dihydroxynaphthalenesulphocarboxylic acids obtained in this way yield mordant dyestuffs when coupled with diazo compounds, the azo group entering the 2- or 7-position without elimination of the carboxyl group (cf. U.S.P. 1,323,285 of 1919; J., 1920, 58 A).

4-Nitro-β-naphthol; Manufacture of —. G. T. Morgan, and British Dyestuffs Corp., Ltd. E.P. 152,437, 17.7.19.

2,4-DINITRO-α-NAPHTHYLAMINE, which may be obtained by the action of alcoholic ammonia at 220° C. on 2,1-dinitro-α-naphthol, or by the nitration and subsequent hydrolysis of aceto-α-naphthalide, is treated with nitrosyl sulphate, or sodium nitrite in concentrated sulphuric acid, and the solution added to water to precipitate 4-nitronaphthalene-1-diazo-2-oxide. On warming this diazo oxide with ethyl alcohol, either alone or in presence of a metallic catalyst such as zinc, copper, aluminium, or a zinc copper couple, or of a reducing agent such as hypophosphorous acid, it is converted into 4-nitro-β-naphthol, which is purified by extraction with hot water from which it crystallises in yellow needles, m.p. 120° C. 4-Nitro-β-naphthol couples with the diazo derivatives of the following compounds giving azo-derivatives which are useful as dyestuffs:—Sulphanilic acid, giving a dark red dye for wool or silk; paranitraniline-2-sulphonic acid, an orange dye for wool or silk; 4,4'-diminostilbene-2,2'-disulphonic acid and safranine, direct purple dyes for cotton or linen; paranitraniline and 2,4-dinitro-aniline, red ingrain dye on cotton; and primuline, a dark blue ingrain dye on cotton; and primuline, a reddish-brown developed dye on cotton.—G. F. M.

Sulphur dyestuff. M. Wyler, Assr. to Levinstein, Ltd. U.S.P. 1,358,490, 9.11.20. Appl., 27.3.19. SEE E.P. 124,589 of 1918; J., 1919, 318 A.

Medicinal preparations. G.P. 324,747. See XX.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Best fibres [nettles]; Retting of —. P. Kraiss. Z. angew. Chem., 1920, 33, 277—278. (Cf. J., 1919, 169 A, 530 A; 1920, 11 A, 443 A.)

BORAX cannot be used as a substitute for sodium bicarbonate because it largely hinders the retting of flax and nettles. At the end of the retting process, the liquors contain chiefly spores and but few pleotridae and rod bacilli. Nettle fibres cannot compete with the usual fibres of commerce, although they may be used in home spinning and weaving. The production of fibres suitable for spinning is carried out as follows:—Nettles are dried, the leaves removed, the stems retted in a 0.8% solution of sodium bicarbonate (if a 0.5% solution of sodium carbonate is used the retting takes longer) at 37° C., dried in the sun, and the bast fibres separated by heating. If the bast fibres be separated by heating with alkalis under pressure, a considerable loss of fibre occurs. Washing and bleaching of the fibres results in a loss of 30—35%. From 100 pts. of air-dried nettles is obtained 5.5 pts. of pure bleached nettle fibres.—A. J. H.

Wool and cotton fabrics; Analysis of mixed —. Duyk. Ann. Chim. Analyt., 1920, 2, 324—330.

THE following is recommended for adoption as a standard method for analysis of textile fabrics composed of a mixture of wool and cotton: From 10—15 g. of the material is cut up and dried at 100°—105° C., and then treated with suitable reagents to remove size, filling material, etc., and again dried and weighed. It is then heated with 2% sodium hydroxide solution in a covered vessel on the water bath to a maximum temperature of 90° C., and 20 mins. after that temperature is reached the cotton residue is washed with acidified water and then pure water, dried, and weighed. The amounts of cotton and wool are then calculated on the basis of the official limits for water, viz., 17% for carded wool, 18.5% for combed wool, 8.5% for cotton, and 10% for silk. For the separation of silk from wool, zinc chloride solution of sp. gr. 1.65 is used.—C. A. M.

Textiles of wool or mixtures of wool and silk; Method of reducing the permeability of —. G. Colombo. Giorn. Chim. Ind. Appl., 1920, 2, 234—237.

TEXTILES of wool or silk and wool are saturated with water, centrifuged to reduce the water content to, e.g., less than 50%, and exposed for 30 mins. in a closed chamber to the action of moist steam between 90° and 100° C. They are then dried within the same limits of temperature. The duration of the treatment required will vary with the size of the chamber, weight of the fabric, and moisture and permeability of the fabric. A woollen fabric thus treated required from 50 to 60 mins. for the filtration of 500 c.c. of water per sq. dem. under a constant pressure of 40 mm., whereas only 13 to 18 mins. was required prior to the treatment.—C. A. M.

Textiles; Laboratory apparatus for determining the permeability and heat-insulating value of —. G. Colombo. Giorn. Chim. Ind. Appl., 1920, 2, 167—168.

THE permeability of fabrics to water is determined by stretching the material across a metal wire framework which fits into a larger vessel so as to form a porous bottom, the overlapping edges being immersed in mercury seals. Water is maintained at a constant level above the stretched fabric, and the amount which filters through the material at a definite temperature is measured and expressed in vols. per sq. dem. of the fabric. In determining

the heat conductivity a cylinder 50 mm. in diam. is filled with mineral oil which can be heated electrically. The cylinder is closed by a cork through which passes a thermometer, by means of which it is suspended in a second metal cylinder with perforated walls, leaving a space of 15 mm. between the two cylinders. The fabric is stretched round the outer cylinder, and the apparatus placed under a bell jar. The time required for the oil to fall through a given range of temperature is then noted.—C. A. M.

Cellulose and textile fibres; Digestion of woody fibres with chlorine for the production of —.

P. Waentig and W. Gierisch. *Text.-Forschung*, 1920, 2, 69—79. *Chem. Zentr.*, 1920, 94, IV., 544.

For the production of cellulose from wood shavings of 0.2–0.3 mm. thickness the authors recommend a preliminary boiling for 1 hr. in 0.1 sodium hydroxide solution, then treatment with chlorine for several hours without heating, and after the removal of hydrochloric acid a final treatment in 1% sodium hydroxide solution at the ordinary temperature with stirring. Thick shavings and chips may be digested with chlorine under 6 atm. pressure. A preliminary heating with 1% alkali is necessary in the treatment of cereal straws. The chlorine process is not suitable for the production of textile fibres from jute and rushes, but it might be applicable to hemp, flax, ramie, and nettles.

—J. H. L.

Cellulose; Action of hydrogen peroxide on —. R. Haller. *Text.-Forschung*, 1920, 2, 79—81. *Chem. Zentr.*, 1920, 94, IV., 543—544.

Most vegetable textile fibres are disintegrated by the prolonged action of 30% hydrogen peroxide and eventually dissolve with formation of dextrose. A cellulose peroxide which reacts characteristically with potassium iodide is formed as intermediate product. The disintegration of the fibres is accelerated by certain cotton dyes and retarded by others. Cotton mordanted with chromium oxide is very rapidly broken down, whilst the simultaneous presence of aluminium has a retarding effect. It is possible that impregnation of laundry goods with alumina may protect them from injury from detergents containing hydrogen peroxide.—J. H. L.

Waste roofing felt. Hawley and Kress. See IX.

PATENTS.

[Pulp] digesters; Acid-charging system for —. F. J. Dooley. U.S.P. 1,338,496, 27.4.20. Appl., 23.5.19.

THE "acid" is fed into the digester at the bottom by means of a pump placed below the level of the liquid in the digester, but the pipe connecting the pump with the digester extends upwards and has a portion above the liquid level in the digester, and preferably above the top of the digester. The control valve is placed in this elevated portion of the pipe. After charging the digester, the valve can be disassembled and packed to render it fluid-tight for the cooking operation without risk of escape of "acid" from the digester.

Pyroxylin; Solvents of — and compositions containing the same. E. M. Flaherty, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,356,410, 19.10.20. Appl., 11.9.18.

The solvent contains *n*-butyl alcohol, a hydrocarbon, and an alcohol of the paraffin series.

—B. V. S.

Fibres; Method of making —. A. R. Fuller. U.S.P. 1,357,206, 26.10.20. Appl., 10.2.20.

FIBRES are obtained from a viscous material such as a solution of cellulose xanthate (viscose) by forcing

the material by means of a centrifugal pump through fine apertures into a coagulating liquid.

—B. V. S.

Sulphite-cellulose waste liquors; Utilisation of —. F. Siemens. G.P. 325,756, 25.12.19.

THE bisulphites and lignosulphonic acids are reduced by treating the liquor with carbon monoxide. Calcium bisulphite yields calcium hydrosulphide and from this hydrogen sulphide may be produced and converted into sulphur or sulphur dioxide. The precipitated wood constituents are directly fermentable.—J. H. L.

Paper; Method and machine for making —. Great Northern Paper Co., Asses. of C. E. Pope. E.P. 137,539, 8.1.20. Conv., 26.3.18.

IN starting the machine or in case of a break, the paper is carried from the drying rolls to and through the calendars by cutting a lead strip and directing it through the machine by a series of doctors and air-blasts; subsequently the strip is widened to the width of the web of paper.

Textile materials treated with Turkey-red oil or the like; Prevention of — acquiring a yellow tint. C. H. Boehringer Sohn. G.P. 325,470, 10.5.19.

THE textile materials are treated with Turkey-red oil or the like in the presence of salts of hydrolysed or non-hydrolysed bile acids. Thus, 2–3% of sodium cholate, or 4–5% of potassium glycocholate may be used.—J. S. G. T.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid manufacture by Schönher's process; Experiments on —. F. Kodera, I. Kitawaki, and B. Yokoyama. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Tokyo), 1920, 23, 1010–1015.

THE diameter of the inner tube of the furnace was 6 in. and the total length of the furnace about 20 ft. In the case when the are was most stable and every other condition was comparatively good the following data were obtained:—Voltage supplied from transformer, about 5000 volts; air quantity supplied per minute, 2000 l.; arc voltage, 2700 volts; intensity of current, 30 ampères; power required, 74 kw.; arc length, 13 ft.; concentration of nitric oxide produced, 1.8% by volume. The gas from the furnace was passed through a multitubular boiler, a water cooler, an oxidation chamber, and three absorption towers. Nitric acid of 42% concentra-

tion could be prepared by absorbing with water, but it would be more economical to stop the absorption when the concentration of the acid has reached about 35%. The theoretical yield of acid was 82 g. per 1 kw.-hr., while the yield actually obtained was about 65 g. Of the energy supplied to the furnace, about 3% was utilised to form nitric oxide, 60% was consumed by the cooling water of the furnace, and 12% by the boiler.—K. K.

Calcium cyanamide; Investigation of preparation and properties of — N. Kameyama. J. Coll. Eng., Tokyo Imp. Univ., 1920, 10, 173—207, 209—247, 249—263.

WHEN calcium cyanamide is prepared by igniting urea with lime, calcium cyanate is formed as an intermediate product at temperatures below 300° C., transformation into cyanamide taking place slowly at 340°—360° C., and rapidly at or above 450° C. The heating should be of short duration to prevent oxidation of the cyanamide; 5—7 mins. at 800° C. is sufficient. The percentage of cyanamide found in the mixed product of calcium cyanamide, calcium carbonate, and calcium oxide depends on the initial proportions of urea and lime. Mixtures of these substances in the proportions of 1:2, 1:1½, and 1:1, give products containing 16.5, 24, and 34% of calcium cyanamide, and 92—98% of the theoretical yield is attained. Ignition in a current of nitrogen gives a quantitative yield. If dicyanodiamide is used instead of urea, although a smaller proportion of the theoretical amount is obtained, the product contains more calcium cyanamide. Even at 300°—400° C. no cyanate is formed. Equal parts of dicyanodiamide and lime should be taken, and in order to decompose the calcium carbonate in the cyanamide mixture the ignition is best conducted at 900°—1000° C. for about 10 mins. The product will contain 50—53% of calcium cyanamide but this amount is increased up to 90% by reheating with excess of dicyanodiamide, and by further heating in a current of nitrogen 99% is reached. The reactions of calcium cyanamide, prepared from dicyanodiamide and lime, with oxygen, carbon dioxide, and carbon monoxide, were investigated on a sample of composition: CaCN_2 , 92.3%; CaCO_3 , 3.97%; CaO , 3.73%. At 420°—450° C. oxygen reacts rapidly with formation of calcium carbonate and nitrogen, but with no separation of carbon; at 840°—900° C. the reaction products consist of calcium oxide, carbon dioxide, and nitrogen. With carbon dioxide decomposition occurs between 700° and 1070° C. with no separation of carbon, the products being carbon monoxide, nitrogen, and calcium oxide or carbonate according to the temperature. Above 1110° C. the reaction is very rapid, and carbon is liberated, probably owing to the decomposition of carbon monoxide. In absence of a catalyst carbon monoxide is without action on calcium cyanamide up to 1000° C., but if carbon dioxide is produced from the monoxide the cyanamide may be indirectly oxidised by it. At temperatures above 1140° C., carbon monoxide decomposes calcium cyanamide, even without aid of catalysts, calcium oxide, carbon, and nitrogen being formed. The heat of combustion of pure calcium cyanamide was found to be 154,730 cals. per g.-mol. at constant pressure; and, calculated from this, the heat of formation is 91,480 cals. from crystalline carbon (diamond), or 94,820 cals. from amorphous carbon.—W. J. W.

Ammonium sulphate; The Feld process for production of — F. Raschig. Z. angew. Chem., 1920, 33, 260—262.

The author has investigated the reactions which occur in Feld's process for the production of ammonium sulphate from the ammonia and hydrogen sulphide present in coke-oven gas (J., 1912,

430). Formation of polythionates by the action of sulphur dioxide on thiosulphate only takes place with very concentrated solution; with dilute solutions sulphite and sulphate are chiefly produced. Addition of a trace of sodium or potassium arsenite ensures the conversion of thiosulphate into tri- and tetrathionate, pentathionate being a probable intermediate. The reactions are based on proportions of ammonia and hydrogen sulphide of 2:1. An excess of either gas retards the conversion, and necessitates in one case the introduction of more hydrogen sulphide, and in the other case its oxidation to sulphur. Careful control and testing of the gases are essential for successful running. (Cf. J.C.S., Jan., 1921.)—W. J. W.

Ammonium sulphate; Melting point and boiling point of — E. Jäcke. Z. angew. Chem., 1920, 33, 278—280.

THE equilibrium between sulphuric acid, ammonia, ammonium bisulphate, and ammonium sulphate has been investigated and the results are shown graphically. Under atmospheric pressure, ammonium sulphate decomposes completely at 357° C. Pure ammonium bisulphate has m.p. 251° C. and b.p. 490° C. (cf. J., 1895, 629; 1896, 3; 1920, 485 A). The melting point curve for mixtures of the acid and normal ammonium sulphates has an eutectic point at 195° C. (Cf. J.C.S., Dec.)—A. J. H.

Sodium hypobromite; Catalytic decomposition of an alkaline solution of — by copper sulphate. Antagonistic action of iodine. P. Fleury. Comptes rend., 1920, 171, 957—960.

THE presence of copper sulphate causes a steady decomposition of an alkaline solution of sodium hypobromite, thus interfering with the estimation of urea by this reagent. The rate of decomposition increases rapidly with the concentration of the copper salt. The presence of 1 pt. of copper in 100,000 causes the decomposition of 42% of the hypobromite in 24 hrs. at 36°—37° C. The addition of 1 pt. in 1000 of potassium iodide or potassium iodate to the solution completely inhibits this catalytic decomposition of the hypobromite solution.—W. G.

Sodium hydrosulphite; Valuation of — R. E. Crowther and A. D. Heywood. J. Soc. Dyers and Col., 1920, 36, 279—281.

TO 800 c.c. of air-free water in a litre flask 40 c.c. of 40% formaldehyde solution and 10 c.c. of 30% sodium hydroxide solution are added, and whilst the contents of the flask are vigorously swirled, 8—12 g. of the hydrosulphite powder, weighed by difference from a stoppered weighing bottle, is rapidly added through a dry funnel, and the volume of the solution finally adjusted to 1000 c.c. This formaldehyde hydrosulphite solution is then run from a burette into 25 c.c. of standard methylene blue solution (about 14 g. per l.), to which 10 c.c. of glacial acetic acid and 50 c.c. of water have been added, the liquid being gently boiled during the titration. The end point is quite sharp, and is indicated by a change from bluish-green to yellow. For very accurate work a stream of carbon dioxide is passed through the flask containing the methylene blue solution, but for technical purposes this is not necessary. Alternatively the formaldehyde-hydrosulphite solution may be added to an excess of methylene blue solution, and the excess titrated with titanous chloride solution.—G. F. M.

Hydrosulphite; Volumetric determination of — R. Formhals. Chem.-Zeit., 1920, 44, 869.

ABOUT 0.5 g. of hydrosulphite is dissolved in 50 c.c. of air-free water and the solution is titrated with N/10 potassium ferricyanide solution in presence of a few drops of ferrous ammonium sulphate solu-

tion as indicator, the end point being indicated by the formation of a permanent blue-green coloration of Turnbull's blue. The reaction is expressed by the equation:—

but in practice it is preferable to standardise the ferrieyanide solution by titration with pure hydrosulphite.—G. F. M.

Gels of earth-acids [titanic, niobic, and tantalic acids]; *Solubility of* — in mixtures of hydrogen peroxide and acid. O. Hahn and H. Gille. Z. anorg. Chem., 1920, 112, 283–292.

According to Weiss and Landecker (J., 1909, 1169), titanic, niobic, and tantalic acids can be separated from most other elements by dissolving the freshly precipitated acids, whether precipitated from acid or basic solutions, in acid hydrogen peroxide and re-precipitating by boiling with sulphurous acid. It is now shown that whilst titanic and niobic acids are practically completely soluble in acid hydrogen peroxide solution, tantallic acid, when precipitated hot, is practically insoluble, and when precipitated cold is very slightly soluble. In mixtures, tantallic acid lowers the solubility of niobic acid. Titanic acid may increase the solubility of tantallic acid or may have its own solubility reduced, according to the conditions of precipitation and the after-treatment of the precipitate. Weiss and Landecker's method therefore fails in presence of tantallic acid. Titanic acid solutions in hydrogen peroxide, examined with the ultramicroscope, appear to be truly molecular, whilst those of niobic and tantallic acids are colloidal.—E. H. R.

Iodic acid; Microchemical reactions of —. A. Bolland. Comptes rend., 1920, 171, 955–957.

A DESCRIPTION is given of the appearance under the microscope of the precipitates given by iodic acid with the following reagents:—Thallium nitrate, silver nitrate, barium chloride, strontium acetate, calcium acetate, rubidium chloride, caesium sulphate, rubidium cadmium chloride, potassium chloride, sodium acetate, ammonia, manganous chloride. The first two reagents give a precipitate with iodic acid diluted to 1 in 5000, the next with 1 in 2500, the next three with 1 in 300, whilst for the remainder the dilution should not be more than 1 in 80 and preferably about 1 in 20.—W. G.

Salts; Action of water on a mixture of —. Determination of the number of independent constituents. C. Raveau. Comptes rend., 1920, 171, 913–916.

A CRITICISM of Dubreuil's rule (Comptes rend., 1920, 171, 720) and a theoretical discussion of Rengade's work (J., 1917, 961) on the purification of salts by fractional crystallisation, in the light of this rule.

—W. G.

Sulphur monochloride; Determination of — in admixture with mustard gas. W. A. Felsing, S. B. Arenson, and F. J. Kopp. J. Ind. Eng. Chem., 1920, 12, 1054–1056

THE method is based upon results which show that sulphur monochloride reacts with sodium iodide as in the equation— $S_2Cl_2 + 2NaI = I_2 + 2S + 2NaCl$. About 25 c.c. of approximately N/10 sodium iodide solution and 10 c.c. of carbon tetrachloride are introduced into a 250 c.c. flask, the flask weighed, 2 c.c. of the mixture of mustard gas and sulphur chloride introduced, and the flask again weighed. A measured excess of sodium thiosulphate solution is then added, and the excess titrated with standard iodine solution. The results are accurate within 0.5% at higher concentrations (20–30%), and to about 0.1% with lower concentrations (2–5%) of sulphur monochloride.—C. A. M.

VIII.—GLASS; CERAMICS.

China clay; Shrinkage, porosity, etc., of — after being fired at various temperatures. E. M. Firth, F. W. Hodkin, and W. E. S. Turner. J. Soc. Glass Techn., 1920, 4, 264—267.

A SAMPLE of china clay of normal composition required 49.5% of water to bring it to a moulding consistency. On being fired its colour changed from creamy white to a slight pink between 600° and 1100° C., but at 1200° C. it was dead-white. The fracture of pieces fired at 1400° C. showed a slight glaze, and at 1500° C. this was more pronounced and the colour bluish-white. The shrinkage remained below 5% up to 1000° C. and then rose very rapidly to 22% at 1500° C. The porosity was 50% at 600° C., rose to a maximum (56%) at 900° C., and then fell rapidly to 2.4% at 1500° C.—A. B. S.

Glass; Drawing —. R. L. Frink. E.P. 144,629, 2.6.20. Conv., 12.6.19.

A HEAD through which air can be supplied and which can be moved into any desired position, is mounted on a hollow standard passing through a cylindrical well of refractory material in the drawing pot. The circular jet of air impinges upon the inner walls of the hollow glass cylinder slightly

below the point of congealing of the glass. The volume, direction, and force of the air can be varied by altering the jet openings and inclining the head, and so the diameter of the cylinder and the thickness and uniformity of its walls can be controlled.—H. S. H.

Non-fragile glass; Manufacture of a — using natural silicates such as micaceous mineral, asbestos, and the like. P. B. Crossley. E.P. 152,780, 22.7.19.

A MIXTURE of the finely divided silicious material and powdered glass or a similar vitreous material is heated at a temperature high enough to melt the glass but insufficiently high to disintegrate the silicious material, until the whole is transformed into a more or less viscid mass. The product may be rolled or forged, or the temperature may then be raised until the mass liquefies and can be cast into moulds. By the addition of colouring matter, a coloured product may be obtained, or by varying the proportions the product may be transparent, semi-transparent, or opaque. The material can be turned and adheres tenaciously to metals and is thus suitable for the manufacture of electric and heat insulators, and for other purposes.—L. A. C.

Refractory article. S. C. Linbarger, Assr. to The Carborundum Co. U.S.P. 1,356,211, 19.10.20. Appl., 21.6.19.

A REFRACTORY article for use in preventing discoloration of ceramic ware in firing, comprises a body containing silicon carbide with a protective coating free from silicon carbide.—H. S. H.

Refractory material. J. L. Ohman, Assr. to N. K. Farish. U.S.P. 1,356,939, 26.10.20. Appl., 1.11.17.

A NON-RECRYSTALLISED refractory material consists of silicon carbide and crystalline graphite.
—H. S. H.

Tunnel-kilns; Method and means for firing —. J. B. Owens. U.S.P. 1,355,906, 19.10.20. Appl., 24.8.18.

A COMBUSTION chamber, communicating at its side with the interior of the tunnel, is provided with means for deflecting the heat and products of combustion into the tunnel. The combustion chamber is fired in the direction of its length.—H. S. H.

Tunnel-kilns; Method of firing — and convertible furnace therefor. J. B. Owens. U.S.P. 1,356,396, 19.10.20. Appl., 23.1.17.

HEAT is supplied to a combustion chamber communicating with the burning chamber from any one of a number of independent sources of fuel differing in kind and extraneous to the combustion chamber.—H. S. H.

Tunnel-kilns; Firing means for —. J. B. Owens. U.S.P. 1,356,397, 19.10.20. Appl., 14.8.18.

A TUNNEL kiln has a multiple firing zone with which combustion chambers communicate at different points of its length. Means for firing the combustion chambers in a direction other than towards their communication with the firing zone are provided. The hot products of combustion are delivered from the chambers on to the lower portions of the ware in the tunnel and are then caused to flow in the same direction through the firing zone. By the arrangement described the goods may be subjected to a relatively long "soaking" heat at the temperature necessary to burn them.—H. S. H.

Tunnel-kiln; Multiplex —. J. B. Owens. U.S.P. 1,356,398, 19.10.20. Appl., 18.2.19.

TRACKS along which cars carry the ware extend side by side along the length of the tunnel kiln.

Closed partitions rise between the car platforms and extend throughout the length of the kiln between the sets of tracks, and those parts of the tunnel which are below the cars can be sealed from those parts which are above the cars. The products of combustion pass lengthwise along the tunnel.—H. S. H.

Ceramic material; Grouped direct-fired furnaces for —. H. Herda. G.P. 324,977, 25.3.19.

COOL air from the cooling furnace of a pair of furnaces is mixed with waste gas from the fired furnace of the pair, in a mixing chamber situated in a common channel placed beneath the furnaces, and the mixture is passed to a preheating chamber. Carbon or soot in the gases is burnt, and any light ash carried by the mixture is deposited in the mixing chamber.—J. S. G. T.

Kiln; Annular —. H. Fehmer. G.P. 325,298, 17.7.18.

THE waste gases from the smoking zone and the firing zone are discharged to the chimney stack through separate flues. Warm gases derived from the cooling and preheating zones are delivered through separate flues to the smoking and drying zone; this air is then in part discharged and in part to the pre-smoking zone.—J. S. G. T.

Tunnel muffle furnace; Heating of —. C. Schürtler. G.P. 325,299, 29.11.17.

THE firing zone, smoking zone, and pre-smoking zone are heated by the furnace gases in the usual manner, but the zone in the immediate neighbourhood of the furnace is heated only by air from the tunnel which has been preheated in the cooling zone and then heated to a high temperature in the firing zone; this air is then in part discharged and in part delivered to the smoking zone.—J. S. G. T.

Glazed or enamelled sheets of iron, steel, etc.; Production of —. A. Meyer. G.P. 325,673, 15.3.13.

THE ground coat of enamel is overlaid with successive opaque layers of enamel composed of silica, aluminium silicate, lead oxide, and an alkali such as sodium borate. Powdered rutile in variable proportion is added to the successive layers in order to increase or diminish their respective plasticities.—J. S. G. T.

Copper deposit on glass etc. E.P. 152,835. See X.

IX.—BUILDING MATERIALS.

Portland cement and puzzuolana; Mixtures of —. F. Ferrari. Giorn. Chim. Ind. Appl., 1920, 2, 238—244.

THE results of comparative tests with pure Portland cement and sand (1:3), and mixtures of Portland cement and puzzuolanas of various origin with sand have shown that puzzuolana and similar materials act as a corrective to the excessive basicity of hydrated calcareous cements of the Portland type, to which cause must be attributed the permeability to dissolved salts of set cements of the latter type. On the other hand, mixtures of Portland cement and puzzuolana, which are more or less rich in calcium aluminates, do not offer sufficient resistance to the action of sea water, but are suitable for all purposes where the cement will not be submitted to the continual action of sulphates and chlorides. Cement made from Portland cement, puzzuolana, and sand in such proportions that the quantity of lime formed on hydration corresponds to the amount which will be fixed by the other ingredients (puzzuolana and sand) is practically impermeable to dissolved salts, and is stronger than Portland cement.—C. A. M.

Waste roofing felt; Recovery of —. L. F. Hawley and O. Kress. Paper, 1920, 27, 18.

WASTE roofing felt, which is at present burnt under boilers at the factories, was extracted with gasoline to ascertain whether a recovery of the material would be practicable on the commercial scale. The waste, cut into pieces about 1 in. square, was extracted three times in succession with gasoline of b.p. 90° to 110° C. in a closed apparatus fitted with a steam-coil and a reflux condenser. At the end of each extraction, the solution was run off from the bottom of the vessel. About 50–60% of pitch, referred to the original material, was removed in this way, and although a considerable amount of matter soluble in gasoline and chloroform remained in the extracted material, this did not interfere with the opening of the latter or with the running of the stock on the paper machine. In the case of shingle stock, the rock could be readily separated after extraction by mechanical means. For a commercial process, four extractions with 350 galls. of solvent per ton of material should yield approximately the same results as those obtained in the laboratory trials.—L. A. C.

PATENTS.

Vesicular product and method of making such product. U. W. Boynton and R. J. Wig. E.P. 153,030 16.4.19.

A SHALE or clay rich in iron and other fluxes (except lime and magnesia) and containing carbon, sulphur, or other substances which at proper temperatures will cause the production of gas, is ground, formed into any required shapes, and heated to incipient fusion. The gases generated cause the material to expand and become full of small cells. The product is strong and tough, has a low apparent specific gravity, is a non-conductor of heat and a good electrical insulator, and is substantially impervious to water under ordinary conditions, as the various cells are not in connexion.—H. S. H.

Moulded articles from acid-proof cement; Manufacture of —. W. E. Windsor-Richards. E.P. 153,017, 21.6.19.

GROUND glass, sand, or quartz is mixed with clay, asbestos fibre, and a solution of sodium silicate, and the wet mixture pressed into moulds. After removal from the moulds, the articles are heated for about 12 hrs., the temperature being gradually raised to 200° C., and are then impregnated with any suitable acid-proof bituminous medium.—H. S. H.

Shaft furnace [for burning powdered limestone]. F. Müller. G.P. 323,339, 20.1.16.

THE furnace has a vertical preheating chamber and a horizontal burning chamber, the horizontal or slightly inclined floor of the latter being formed by a mechanical conveyor which transports the powdered material through the chamber in thin layers.—J. S. G. T.

Weather-resisting building material; Production of —. M. Künkele. G.P. 325,777, 26.9.19.

A WEATHER-resisting building material with properties resembling those of cement is produced by firing together broken stones, pyrites, clinker, and trass or material with similar properties, together with shale, to which, if it contains but little chalk, some chalk is added.—J. S. G. T.

Orysalt [cement] compositions and processes of making same. C. Catlett. E.P. 126,646, 9.5.19. Conv., 9.5.18.

SEE U.S.P. 1,282,188 of 1918; J., 1919, 17 A.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Thermal analysis; Sensitive method of — and the transformations of quartz, iron, and nickel. A. Perrier and F. Wolfers. Arch. Sci. Phys. Nat., 1920, 125, 372—381.

A NEW differential method is described for studying heat transformations. Two identical specimens of the material to be examined were suspended in an electric furnace at different levels, so that there was always a small temperature difference, preferably about 10° , between them. In each specimen was inserted a thermo-couple, by which the temperatures were read during heating or cooling, and the temperature differences were plotted on a curve against time. At temperatures corresponding with changes of state in the materials, marked sinuositics appeared on the curve. By this means slight thermal effects were detected which are not apparent on an ordinary cooling curve. In the case of quartz the α - β change was shown by a very prominent sinuosity which appears to indicate a change of latent heat. With soft iron a very complex curve was obtained which, besides the usual thermal changes, showed irregularities at about 800° C. and just above 1100° C. The former appears to correspond with a change in magnetic susceptibility observed by Weiss and Foëx (J. de Phys., 1911. (5). I., 274, 744, 805), whilst the latter appears not to have been observed before. Nickel gave a simpler curve than iron. Two new thermal transformations were discovered, however, one at about 460° , which corresponds with the magnetic change observed by Weiss and Foëx (*loc. cit.*), the other near 890° C., corresponding with a discontinuity of Curie's constant observed by Bloch (Thesis, Zurich, 1912).

—E. H. R.

Corrosion of iron in sulphuric acid; Effect of chromium compounds on the —. G. W. Heise and A. Clemente. Philippine J. Sci., 1920, 16, 439—446.

THE influence of the addition of graduated amounts of potassium bichromate on the corrosion of iron in sulphuric acid of varying strengths has been investigated. With both $N/2$ and $N/1$ sulphuric acid corrosion increased in proportion to the amount of bichromate added up to a maximum at which passivity was reached, after which corrosion decreased. With $N/2$ acid the passive condition was obtained with bichromate concentrations above 19 g. per l.; with $N/1$ acid the results were irregular, but in individual cases passivity was observed at a concentration of about 50 g. per l. In the case of $2N$ sulphuric acid, addition of potassium bichromate even up to its saturation point failed to bring about a passive state; corrosion increased without subsequent diminution. The addition of a small amount of potassium bichromate or of potassium chromate to 10% sulphuric acid increased the corrosion of iron at first, but when reduction of the chromium salts had taken place, the rate of corrosion did not differ from that in sulphuric acid alone. Chromium compounds such as the sulphate, introduced as chromic hydroxide, and chloride, apparently exert no influence on the rate of corrosion.—W. J. W.

Steel; Determination of vanadium in —. E. Jaboulay. Rev. Mét., 1920, 17, 627—629.

ONE g. of the metal (or 0.5 g. if more than 2% V is present) is dissolved by heating with 50 c.c. of dilute sulphuric acid, the solution is oxidised with nitric acid, and any insoluble black residue is dissolved by adding small successive quantities of permanganate solution to the boiling mixture; the solution is then diluted to 200 c.c., boiled, filtered, and, if chromium is present, the cold filtrate is titrated

with ferrous sulphate and permanganate solutions. The solution is then diluted to at least 300 c.c., and $N/10$ ferrous sulphate solution is added until present in slight excess (about 0.5 c.c.), using ferricyanide as external indicator; the mixture is further diluted to 500 c.c., the excess of ferrous sulphate is oxidised by the addition of 1 c.c. of $N/10$ bichromate solution, and the vanadyl salt is titrated with permanganate solution. The number of c.c. of $N/10$ permanganate solution used is multiplied by 0.511 to obtain the percentage of vanadium.—W. P. S.

Chromium and tungsten steels containing double carbides. P. Oberhoffer and K. Daeges. Stahl u. Eisen, 1920, 40, 1515—1516.

THE influence of chromium and tungsten on the saturation limits of carbon in γ -iron was investigated by microscopical examination. The alloys were made from pure materials, and to ensure obtaining equilibrium conditions they were thoroughly annealed at 800° C. for 14 hrs., or in the case of alloys containing a small amount of eutectic at 1100° C. for a longer period. After annealing, the steels were forgeable, specially those in the martensitic region of Guillet's structural diagram (*cf.* J., 1910, 953). Steels with 0.3—0.5% C and 15—20% Cr showed after suitable treatment great resistance to oxidation and attack by acids. In the chromium steels the eutectic was scarcely distinguishable from ledeburite, but clearly distinguishable in the tungsten steels. The results obtained show that the saturation limit of carbon falls from 1.7% to about 0.9% in presence of 2% Cr or to 0.8% in presence of 2% W, and more slowly to about 0.1% at 13.8% Cr or 0.13% at 12% W. On appearance of the eutectic, extra care must be given to the choice of forging temperature. The degree of working necessary to obtain uniform distribution of the carbide and destruction of the cellular structure of the eutectic is proportional to the amount of eutectic present.—T. H. Bu.

Arsenic and phosphorus; Determination of — in metallurgical products. I. Compagno. Giorn. Chim. Ind. Appl., 1920, 2, 493—497.

THE distillation method of Lundin and Blair (Carnot, *Méthodes d'anal. des fontes, des fers, et des aciers*, 1895) is simplified, and copper is used as the reducing agent. Five g. of the finely divided metal is dissolved in dilute (1:1) nitric acid, with the subsequent addition of 10 c.c. of sulphuric acid. The solution is evaporated, and the residue calcined, ground, and again calcined until white fumes appear. The mass is dissolved in 200 c.c. of hydrochloric acid, and transferred to a distillation apparatus, and, after the introduction of 5 g. of pure copper turnings, the arsenious chloride is distilled into 300 c.c. of water chilled in ice-water. The arsenic in the distillate is precipitated cold as sulphide, the excess of hydrogen sulphide removed by means of carbon dioxide, and the arsenic sulphide collected in a Gooch crucible, washed with water, alcohol, and carbon bisulphide, dried, and weighed. For the determination of phosphorus when arsenic is present in any considerable quantity, an aliquot portion of the distillation residue is filtered from silica, the filtrate oxidised by means of nitric acid and potassium permanganate, and the phosphorus determined by one of the usual methods. If arsenic is not to be estimated, it may be removed by volatilisation by the action of hydrobromic acid on the hydrochloric acid solution of the alloy, or after reduction with pure copper.

PATENTS.

Iron composition. G. G. Marx. U.S.P. 1,339,469, 11.5.20. Appl., 16.6.19.

A FINE-GRAINED, soft, scaleless cast iron is made by melting a charge consisting of pig-iron (35%), scrap iron (60%), and a clay product, *e.g.*, firebrick (5%), to which may be added 5% of steel.

Nickel-steel; Manufacture of — P. F. Cowing, Assr. to H. F. Chappell. U.S.P. 1,356,312, 19.10.20. Appl., 16.6.20.

AN alloy of nickel and copper, obtained from nickel-copper matte, is dissolved electrolytically, the copper in the resulting solution is replaced by iron or by iron and nickel, and afterwards an alloy of nickel and iron is deposited from the solution electrolytically and incorporated with steel to produce nickel-steel.—J. H. L.

Molybdenum compounds; Extraction of — from yellow lead ores [wulfenite]. Deutsche Molybdaen-Werke G.m.b.H. E.P. 131,897, 27.8.19. Conv., 23.5.16. (Cf. E.P. 131,898; J., 1920, 724A.)

FINELY powdered ore is agitated with an excess of an aqueous solution of an alkali sulphide, polysulphide, or hydrosulphide, either hot or cold, and with or without pressure. The solution, which contains sulphomolybdate, is treated with a fresh charge of ore or with a lead salt or ferric hydroxide to remove the sulphur and leave a solution of alkali molybdate.—A. R. P.

Zinc sulphide ores; Roasting of — preparatory to leaching. Electrolytic Zinc Co. of Australasia Proprietary, Ltd. E.P. 131,825, 9.10.19. Conv., 7.11.18.

ZINC sulphide ores are roasted at a high temperature until the sulphur present as sulphide is reduced to 6–10%, the air supply is then increased, and the temperature allowed to fall to 650°–750° C., whereby a large proportion of the remaining sulphur is converted into sulphate. At the end of the first operation the charge may be mixed with a proportion of ore which has already been through the sulphating process. Alternatively the first operation may be prolonged until the ore is roasted "sweet," when it is mixed with sufficient unroasted ore to bring the amount of sulphur present as sulphide up to 6–10% and subjected to the sulphating roast; or, preferably, the unroasted ore is added in several lots during the second roasting operation so that the proportion of sulphide sulphur in the charge never exceeds 2%.—A. R. P.

Zinc solutions; Treatment of — F. Petersson, and The Metals Extraction Corp., Ltd. E.P. 152,752, 17.7.19.

DISSOLVED silica is precipitated from zinc solutions by treating the neutralised or substantially neutralised solution with a slight excess of an alkali or alkaline-earth carbonate at 90°–100° C.—J. W. D.

Furnace; Smelting — heated by oil or gas. K. Schmidt. E.P. 152,697, 25.3.18.

IN a furnace having an outlet shaft in the middle of the smelting chamber, the top or cover is made to slope downwards or the bottom to slope upwards so that the distance between the bottom and top of the chamber is smaller near the outlet shaft than at the outer walls. The inlet pipes or passages for the oil or gas are arranged in oblique or tangential relation to the outer wall so as to produce a whirling effect on the gases.—J. W. D.

Amalgam presses. S. H. Cocks. E.P. 152,815, 9.8.19.

A FILTER-PRESS to separate excess of mercury from amalgam consists of a chamber provided with a removable screwed airtight cap, and a perforated base

secured to the chamber by means of a removable clamp, and having a valve-controlled inlet pipe for introducing fluid under pressure to the interior of the chamber. The perforated base is covered by a filtering medium, such as canvas, through which the mercury is forced by the fluid under pressure introduced into the chamber.—J. W. D.

Copper; Deposition of — on non-conducting surfaces. J. D. Smith. E.P. 152,835, 5.9.19.

A STRONG solution of copper sulphate is added to a strong solution of hydrazine sulphate till a pale-blue powder is precipitated. This powder is then suspended in water and treated successively with a solution of ammonia, a solution of caustic soda, and a small quantity of hydrazine sulphate, yielding a clear liquid which deposits a coherent coating of copper when heated in contact with surfaces of non-conducting materials such as glass, porcelain, etc.—J. W. D.

Metallic reflectors; Manufacture of — S. O. Cowper-Coles. E.P. 152,860, 15.10.19.

IRON is deposited electrolytically upon a glass matrix or cathode which has been coated with silver, the deposited iron with the silver coating is removed from the glass cathode, the silver removed from the iron deposit, the deposit sherardised, and the sherardised face polished to form the reflecting surface.—J. W. D.

Aluminium; Process for tinning — A. L. Page, Assr. to S. Rubin. U.S.P. 1,339,710, 11.5.20. Appl., 30.9.19.

THE aluminium to be coated is rubbed until thoroughly clean whilst immersed in molten stearic acid, after which it is removed, heated in a non-carbonising flame, and then immersed in a bath of tin (80%), zinc (10%), aluminium (8%), and "phosphate-tin" (2%).

Magnesium powder; Apparatus for the manufacture of — D. S. Nicol, Assr. to American Magnesium Corp. U.S.P. 1,356,780, 26.10.20. Appl., 23.7.17.

THE apparatus consists of a crucible with an outlet at the bottom through which the metal is discharged into a disintegrating chamber where it meets a jet of fluid. The chamber is provided with a removable cup at the lower end in which the powdered metal collects.—A. R. P.

Mineral flotation; Process for — J. P. Ruth, jun. U.S.P. 1,356,832, 26.10.20. Appl., 21.2.20.

NAPHTHALENE is used as frothing agent.—A. R. P.

[Nickel-chromium steel] shells; Manufacture of — R. A. Hadfield. U.S.P. 1,357,705, 2.11.20. Appl., 10.8.17. Renewed 17.9.20.

Dry cells; Electric —. Burgess Battery Co., Assces. of A. W. Schorger. E.P. 135,502, 19.11.19. Conv., 19.11.18.

A DRY cell is constituted of an outer zinc electrode and an inner fragile moulded cathode encased in a bibulous envelope consisting essentially of plaster, to which preferably starch and borax are added to retard setting. The gelatinisable electrolyte employed is preferably composed of a solution containing about 25.5% of cereals such as starch, meal, or maize, and 36.7% of zinc and ammonium chloride (see E.P. 128,332; J., 1919, 686 A).—J. S. G. T.

Galvanic batteries. G., L., and G. J. A. Fuller. E.P. 152,818, 13.8.19.

A DRY galvanic battery of the type described in E.P. 102,294 (J., 1917, 38) is constituted of an inner carbon electrode and an outer zinc electrode, separated by a dry electrolyte composed of an excitant such as ammonium chloride, of a less hygroscopic nature than zinc chloride, together with gum tragacanth, tapioca, or similar absorbent material, the constituents being dried before mixing. If desired, a little zinc chloride may be added to the depolariser employed, the mixture being subsequently dried. The cell is rendered active when required by addition of water.—J. S. G. T.

Cell; Electric —. C. Féry. U.S.P. 1,356,977, 26.10.20. Appl., 19.2.18.

A FLAT horizontal zinc electrode rests on the bottom of a vessel and is covered by a solution saturated with zinc chloride. The exciting solution of ammonium chloride is of lower density than the zinc chloride solution and floats upon the latter. A vertical tubular carbon electrode rests upon the zinc electrode with a strip of porous insulating material in between, the major portion of the carbon electrode being outside of the dense liquid layer at the bottom of the vessel.—J. S. G. T.

Battery; Electric —. H. F. French, Assr. to National Carbon Co., Inc. U.S.P. 1,357,160, 26.10.20. Appl., 17.2.16.

THE tendency of the electrolyte to become progressively more basic during the life of the battery is reduced by the addition of an organic substance from which an acid is formed under the action of nascent hydrogen.—J. S. G. T.

Electrolytic apparatus. E. A. Ashcroft. E.P. 152,879, 9.7.19.

AN electrolytic apparatus, primarily designed for the electrolysis of magnesium chloride in accordance with E.P. 152,402 (J., 1920, 788 A) consists of a pair or several pairs of cells connected in series and provided with pockets communicating with the bottom of each cell. A weir extends across each cell at the height to which the alloy (used for collecting the separated magnesium) has to rise in the cell. Anodes of graphite or other material are suspended from the covers of the primary cells of

the pairs, while the iron or steel cathodes in the secondary cells are carried in sets attached to supplementary covers which are applied to openings in the main cover, the whole series of covers being included in the electric circuit. The supplementary covers are connected with the main cover by a flexible conductor.—J. S. G. T.

Electrolytic cell with multiple diaphragms. A. Barth. G.P. 325,313, 28.1.19.

LATTICE frames of which the horizontal septa are at various heights are introduced into the electrolyte between the diaphragms.—J. S. G. T.

Electrodes in electric furnaces; Suspension of —. Det Norske Aktieselskab for Elektrokem. Ind. Norsk Industri-Hypotekbank. E.P. 138,354, 28.1.20. Conv., 28.1.19.

AN electrode without a metallic core or casing, which is baked in the electric furnace in which it is used, is composed of a lower hard part and a comparatively soft upper part. It is suspended within the furnace by attaching an external or internal holder to the lower hard part of the electrode, so that the comparatively soft portion is in compression. In this manner, difficulties encountered in the use of cored electrodes such as those described in E.P. 116,853 (J., 1918, 429 A) are obviated. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 116,853; *loc. cit.*)

XII.—FATS; OILS; WAXES.

Fats and oils; Rapid determination of water in —. H. Oertel. Chem.-Zeit., 1920, 44, 854.

THE rise in temperature occurring when 10 c.c. of oil containing water is mixed with a definite quantity of a mixture of anhydrous magnesium sulphate, 2, and kieselgub, 1 part by weight, is a measure of the amount of water present. The

percentage of water is found by reference to tables compiled from results obtained with oils containing known quantities of water. Each 1% of water causes the temperature to rise approximately 1.3° C. Fats should be dissolved previously in an equal weight of an anhydrous solvent.—W. P. S.

Fish oils; Separation of the highly unsaturated fatty acids in —. M. Tsujimoto, Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Tokyo), 1920, 23, 1007—1010.

The method depends on the ready solubility of the lithium salts of the highly unsaturated acids in acetone containing a little water (95% acetone by vol.) and the insolubility or slight solubility of the saturated and less unsaturated acids in the same solvent. The lithium salts may be prepared by neutralising an acetone solution of the acids with lithium hydroxide, using phenolphthalein as indicator, or, for larger quantities, by treating an alcoholic solution of potassium salts of the acids with lithium acetate. The method may be used for approximate quantitative determinations. The amounts of highly unsaturated fatty acids in fish oils determined by the method are remarkably higher than those calculated from the yields of the fatty acid polybromides. On applying the method to vegetable and terrestrial animal oils, comparatively small yields of acetone-soluble salts were obtained. The formula, $C_{22}H_{32}O_2$, is proposed instead of $C_{18}H_{28}O_2$ for clupanodonic acid isolated from Japanese sardine oil. This oil probably contains also another highly unsaturated fatty acid of the composition, $C_{20}H_{30}O_2$.—K. K.

Acid earth [fullers' earth]; Property of — and its application in hydrogenation of oils. [Characters of dike whale oil.] S. Feno, Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Tokyo), 1920, 23, 1028—1033.

METALLIC soaps and other impurities in oils, which act as catalyst poisons during hydrogenation, can be removed by treating the oil with 10% of acid earth (fullers' earth) at 120° C. for 20 mins. If hardened oils are treated with the acid earth, their content of nickel or other mineral matter is markedly reduced.

Dike whale (*Bolocnptera borealis*, Lesson) oil had the following characters:—sp. gr., 0.9224 at 15°/4° C.; acid value, 0.24; saponif. value, 185.2; iodine value, 144.2; acetyl value, 3.2; Hehner value, 96.0; n_D^{20} =1.4751; butyrometer reading at 20° C., 75°, and unsaponifiable matter, 0.7%. The hardened oil had m.p. 58° C.; acid value, 0.4, and iodine value, 3.0.—K. K.

Sugar-cane wax; Constituents of —. J. E. Q. Bosz, Arch. Suikerind, Nederl.-Indië, 1920, 28, 974—977.

A SAMPLE of cane wax extracted from the mud resulting from the defecation of juice in a Java factory was found to have m.p. 60°—62° C., acid value 47.3, and saponif. value 177. Cholesterol was absent. The fatty acids separated by saponifying, adding hydrochloric acid, and shaking out with benzene, had m.p. 51° C., and appeared to be an eutectic mixture of palmitic and stearic acids. In the liquid obtained on steam-distilling the product of saponification, myricyl alcohol, caproic acid, and formic acid were identified. Acetic, benzoic, and cinnamic acids could not be detected.—J. P. O.

Fluidity of oils. See IIA.

PATENTS.

Nickel carbonyl in hydrogenation processes; Method of applying —. R. Lessing, E. P. 152,740, 15.7.19.

NICKEL carbonyl is separated from admixed gases,

e.g., carbon monoxide, by passage over a cooled absorbent such as "activated" charcoal or an inert porous material, such as coke, impregnated with ground-nut (arachis) oil or the like. As soon as absorption is complete a supply of the hydrogenating gas (hydrogen) is passed through the apparatus, which is heated to about 100° C., whereby the absorbed nickel carbonyl is liberated and carried away by the hydrogenating gas.

—L. A. C.

Oil press; Automatic continuous hydraulic —. C. D. Helm and W. A. Diboll, E.P. 153,090, 29.7.19.

THE oil-bearing seed is brought under the press in a series of containers carried by a conveyor. Automatic arrangements are provided to stop the conveyor at the correct point, to lower the hydraulic cylinder (the ram being fixed) and effect the pressing, to raise the cylinder, and re-start the conveyor.

—B. M. V.

Beeswax; Apparatus for extracting and purifying —. L. H. Willis, E.P. 152,811, 12.9.19.

THE crude wax combs are placed in a perforated container, which is fixed in the bottom of an outer vessel, and sufficient water is added to cover the container. On heating the water the wax melts and rises through the perforations to the surface of the water.—L. A. C.

Fats; Recovery of — from waste liquids [by settling and skimming]. J. Blunn, E.P. 153,372, 31.7.19.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Tungsten pigments. H. A. Gardner and A. Reilly, Paint Manufacturers' Assoc., U.S.A. Circ. 109, Oct., 1920, 9 pp.

A BY-PRODUCT from the manufacture of tungsten lamp filaments, containing 99.9% WO_3 , was a light canary-yellow powder of sp. gr. 5.75. It had a negligible tinting power in comparison with chrome yellow. When used as a pigment with linseed oil the oxide changed to a grayish-yellow colour when exposed to the direct rays of the sun for 15 mins. Another product from the same source contained 115% WO_3 together with large amounts of iron and manganese. It was of dark brown colour, very finely divided, and had sp. gr. 4.75. It possessed good staining and drying powers, and when heated with linseed oil it showed a good siccativ action, probably due to its high manganese content.—A. de W.

Mineral spirits as thinners; Solvent properties and colour effects of —. H. A. Gardner and P. C. Holdt, Paint Manufacturers' Assoc., U.S.A. Circ. 107, Oct., 1920, 9 pp.

SHORT-OIL varnishes free from thinner when mixed with different samples of mineral spirit, and allowed to stand for one month in tall glass-covered receptacles, showed varying degrees of darkening of colour. The darkening is attributed to combination between the lead drier of the varnish and sulphur compounds in the thinner. Elastic varnishes free from thinner mixed more readily with turpentine than with any of the mineral oil

thinners, separation of dark material or darkening of colour occurring with the latter after one month's standing. When highly heat-treated oil to which lime had been added during treatment was thinned with an equal weight of mineral thinner, and allowed to stand for one month, a flocculent layer insoluble in excess of thinner separated. With mixtures containing 10–20% of thinner, however, no separation occurred with the mineral spirit thinner, but turpentine caused a separation when added in quite small proportion. Whilst turpentine mixes quite readily with blown oils in all proportions, most samples of mineral spirits cause a cloudiness to develop on standing.—A. de W.

PATENTS.

Ultramarine; Process for the manufacture of —. J. B. Guimet and A. Guillochin. E.P. 152,916, 14.2.20.

In the manufacture of ultramarine an alkali bisulphite or sulphite, such as the sodium sulphite obtained as a by-product in the manufacture of phenol, is used instead of sodium sulphate and/or sodium carbonate. A mixture of 150 pts. of kaolin, 115 pts. of sodium sulphite, 21 pts. of resin, and 200 pts. of sulphur is heated for 6 to 12 hrs. at 850° C., and is cooled during 5 to 6 days or 20 days to produce respectively a green or blue product.

—L. A. C.

Aldehyde condensation product capable of technical utilisation; Manufacture of —. H. John. U.S.P. 1,355,831, 19.10.20. Appl., 25.10.19.

An aliphatic aldehyde is caused to react upon substances containing "carbonic acid amides" in a highly heated state without the use of a condensing medium.—A. de W.

Coating composition; Liquid —. A. N. McKay and W. L. Willis. U.S.P. 1,356,380, 19.10.20. Appl., 21.11.17.

Tar oil and "holder oil" are mixed in a cold still, solutions of granulated caustic soda and potassium permanganate together with milk of lime added, and the mixture heated approximately to 200° F. (93° C.). The residue is subsequently maintained at about 150° F. (65° C.) until all water is evaporated.—A. de W.

Itiopone; Manufacture of —. J. L. Mitchell. U.S.P. 1,356,387, 19.10.20. Appl., 20.8.18.

A product consisting of barium sulphate and zinc sulphide is washed, dried, and pulverised, and then calcined, with agitation, in a muffle furnace, quenched in cold water, and dried.—A. de W.

Stain for wood; Preparation of a substance suitable for producing a durable —. K. S. Fuchs. G.P. 325,731, 5.6.19. Addn. to 320,011 (J., 1920, 665 A).

The waste liquor from the alkaline digestion of vegetable matter, more especially straw, or a solution in alkali of the constituents of the liquor which are precipitated by acid, is treated with salts of heavy metals, such as ferric chloride or copper sulphate, whereby products are obtained which are converted into complex substances soluble in water by treatment with ammonia or amino-bases. The solutions of the products give clear brown tints when painted on wood, and the colour becomes quite insoluble after drying in sunlight or at 50° C.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Latex; Viscosity of — and its bearing on the rate of cure. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, 214–215.

VARIATION in the fluidity of latex is not due to variation in the rubber content, but is caused by incipient coagulation. Viscous latex frequently yields a rapidly vulcanising rubber, possibly on account of bacterial action commencing at an earlier stage than usual.—D. F. T.

Alum as a [rubber] coagulant. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, 142–144.

COAGULATION with the minimal amount of alum, to effect complete separation of the rubber from latex containing a very small proportion of sodium sulphite, gives a product of the same rate of vulcanisation as one obtained under similar conditions with acetic acid as coagulant. In the absence of sodium sulphite, the use of alum causes a retardation of the rate of vulcanisation relative to the effect with acetic acid, but coagulation with sulphuric acid produces a still greater retardation.

—D. F. T.

Latex coagulated with a saccharated solution of lime. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, 144.

The yield of crêpe rubber obtained on coagulating latex with a solution of lime and sugar (saccharated solution of lime, B.P.) was 2% less than the normal; the rubber gave an acetone extract of 3.4% and was of good quality, with a somewhat higher breaking strength and greater rate of vulcanisation than the average.—D. F. T.

[Rubber:] Maturation [of —]. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, 212–214.

"MATURED" rubber obtained by spontaneous coagulation of latex has approximately the same rate of vulcanisation as material produced under similar conditions, but with the addition of a little acetic acid; vulcanisation proceeds more rapidly, however, the thinner the sheet during the maturing process. These and earlier results indicate that both aerobic and anaerobic changes are involved in maturation, but that the alteration is mainly of the latter type.—D. F. T.

[Rubber:] Effect of acids in retarding the rate of cure [of —]. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, 343–347.

If freshly coagulated rubber is soaked in a solution of an acid its rate of vulcanisation is decreased; sulphuric acid exerts a much more marked effect than acetic acid. The effect arises merely from the retention of part of the acid by the rubber because, by soaking in water for several months, it is possible to remove part of the acid and to increase the rate of vulcanisation of the rubber.—D. F. T.

Rubber; Variation in fine hard Parà and plantation —. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, 347–350.

AN examination of the rate of vulcanisation of rubber from five leaves of wild Parà rubber revealed a variation comparable with that observed with properly prepared smoked sheet plantation rubber (cf. Eaton, Grantham, and Day, J., 1919, 111 A).

—D. F. T.

Rubber; Ageing of vulcanised plantation —. H. P. Stevens. Bull. Rubber Growers' Assoc., 1920, 2, 270–276.

EARLIER observations (J., 1918, 305 T, 340 T) have been extended by experiments with three mixtures of rubber 60, sulphur 3, and zinc oxide 37 parts, the rubber consisting of plantation pale crêpe,

plantation smoked sheet, and fine hard Pará rubber respectively. When kept in a vulcanised condition for 3½ years the coefficient of vulcanisation underwent a distinct increase, the extent of which (an average of 0.27 for an initial coefficient of 2–3 and 0.40 for 3–4) was rather greater than that observed with the earlier mixture of rubber 90% and sulphur 10% at a comparable initial degree of vulcanisation. Physical tests after an ageing period of 120 weeks showed that, if the initial coefficient did not exceed 3.5, the breaking strain first increased to a maximum and then began to decrease, the highest final values being obtained for the samples with the lowest coefficients. The initial breaking strength and elongation of each of the mixtures containing zinc oxide, unlike those of a simple rubber-sulphur mixture, were very similar whatever the degree of vulcanisation, the smoked sheet rubber giving the highest breaking strain and the lowest extensibility. The curves representing the alteration of tensile strength and elongation with ageing tend towards a horizontal course after the breaking strength has fallen below 600 g. per sq. mm. For relative stability in vulcanised mixtures of this type it is found that the coefficient of vulcanisation should not exceed a value of 2–2.5, this limit being lower than for a mixture of 90% rubber with 10% of sulphur.—D. F. T.

Rubber analysis. A. R. Pearson, Analyst, 1920, 45, 105–109.

Determination of total sulphur.—20 c.c. of nitric acid (sp. gr. 1.5) is placed in a flask and 0.5 g. of the rubber is added in small pieces at a time; the mixture is heated gradually and kept on a water-bath for 30 mins. Small successive quantities of permanganate are added until some manganese oxide remains unreduced after 1 hr.'s heating, 20 c.c. of concentrated hydrochloric acid is added, the mixture again heated, evaporated to dryness, the residue treated with hydrochloric acid, again evaporated, the residue treated with hot dilute hydrochloric acid, the solution filtered, and the sulphuric acid in the filtrate determined gravimetrically. *Determination of carbonates in rubber mixings.*—1 g. of the finely divided sample is heated with 25 c.c. of glacial acetic acid in a flask provided with a short reflux condenser, the latter being connected with a U-tube containing solid lead acetate, a U-tube containing in one limb sodium acetate and in the other calcium chloride, and two weighed tubes containing soda-lime and calcium chloride. The contents of the first two U-tubes must be saturated with carbon dioxide before use. A current of air is aspirated through the apparatus during the whole operation.

XV.—LEATHER; BONE; HORN; GLUE.

PATENTS.

Chamois leather substitute; Production of a —. O. Röhm. G.P. 325,881, 21.2.19.

A CHAMOIS leather substitute, which closely resembles the genuine material as regards softness

and tenacity, is produced by treating skins with a mixture of soap, fat, and an aldehyde, specially formaldehyde.—W. J. W.

Glue; Production of bone or hide — which remains liquid in the cold. Luftfahrzeugbau Schütte-Lanz. G.P. 325,216, 21.11.17.

Formic acid or a formate is added to the glue dissolved in warm water. Concentrated glue solutions can thus be maintained fluid even below 0° C.

—J. H. L.

XVI.—SOILS; FERTILISERS.

Superphosphates; Retrogradation of —. A. Aita. Giorn. Chim. Ind. Appl., 1920, 2, 227–233.

THE transformation of the monocalcium phosphate in superphosphates into dicalcium phosphate, and of the latter into tricalcium phosphate is commonly attributed to the presence of iron and aluminium in the phosphorites. Experiments described in detail have shown that the presence of free phosphoric acid tends to neutralise the action of the iron and aluminium compounds, and that eventually equilibrium is established. Hence, when phosphorites containing relatively large amounts of iron and aluminium are used in the manufacture, sufficient sulphuric acid should be used to leave a certain quantity of free phosphoric acid in the product.—C. A. M.

Nitrogen; Gas-volumetric determination of ammoniacal, nitric, and organic — in mixed fertilisers. P. Baddi. Giorn. Chim. Ind. Appl., 1920, 2, 376–378.

TEN g. of the fertiliser is extracted with hot water, the extract filtered, and the filtrate and washings made up to 200 c.c. Ammoniacal nitrogen is determined in 10 c.c. by the hypobromite method. Nitric nitrogen is determined by reducing 50 c.c. of the solution with Devarda's alloy in presence of sodium hydroxide, and the ammonia estimated as before. Organic nitrogen is determined by Kjeldahl's method in the solution, and in the residue from the extraction, the ammonia being estimated by the hypobromite method. The results are somewhat lower than those obtained by distilling the ammonia, but for most purposes are sufficiently accurate.—C. A. M.

Calcium cyanamide. Kameyama. See VII.

PATENTS.

Nitrogen compounds; Recovery of soluble — from solutions [sewage]. E. H. Richards and H. B. Hutchinson. E.P. 152,387, 14.6.19.

SEWAGE, or other dilute solution containing ammonium salts, preferably containing less than 0.1% of soluble nitrogen, is maintained under aerobic conditions in contact with activated carbonaceous material, e.g., activated straw, until the latter has become fully loaded with insoluble nitrogen produced from the soluble nitrogen in the liquid, or until the major part of the soluble nitrogen in the liquid, e.g., 90% or more, has been transformed into insoluble compounds by the bacteria. The carbonaceous material may be activated by prolonged contact, e.g., for 90 hrs. or longer, with a dilute solution of soluble nitrogenous compounds, and after use it is available as manure.—J. H. L.

Fertilisers; Production of mixed —. E. Reinau. G.P. 324,379, 13.8.18.

A SOLUTION of an alkali sulphate in heated aqueous nitric acid is caused to crystallise with agitation, at a temperature at which the mother liquor will be saturated or supersaturated not only with alkali nitrate, but also with polysulphate. The crystals

which separate are neutralised with ammonia. In this manner a mixture of potassium nitrate and ammonium sulphate with the same nitrogen content as 96–99% potassium nitrate may be obtained.

—J. S. G. T.

Fertiliser. J. R. Partington and L. H. Parker. U.S.P. 1,348,578, 3.8.20. Appl., 12.12.18.

VII.—SUGARS; STARCHES; GUMS.

Oxalic acid; Presence of — in the sugar cane. J. E. Q. Bosz. Arch. Suikerind. Nederl.-Indië, 1920, 28, 969–974.

OPERATING upon about 15 kg. of the 100 P O J variety of sugar cane, and applying the procedure recommended by Berthelot and André (Comptes rend., 1885, 101, 354), the author has found 0.014% of oxalic acid ($C_2H_2O_4 \cdot 2H_2O$) to be present in water-soluble form.—J. P. O.

Beet juice; Extraction of — by the "rapid" method. S. Thielér. Centr. Zuckerind., 1920, 28, 468–470, 492–495, 522–524.

EXPERIMENTS have been made in several factories in Germany with the so-called "rapid" method, in which after preheating by Bosse's scalding process (U.S.P. 1,005,931; J., 1911, 1326) the slices are extracted by means of Paschen's inclined trough apparatus (U.S.P. 1,134,152; J., 1915, 567), the juice and slices being forced from one end to the other in counter-current through a series of compartments. In the Bük factory, in which a trough about 22 m. long, divided into 20 compartments, was used, the sugar content of the treated slices was found to be 0.4% (calculated on the weight of sliced roots); but the density of the juice finally drawn off, which amounted to 140% on the roots, was about 3° Brix less than in the case of the liquid extracted by the diffusion method. The purity of the juice was about the same as in the diffusion process; but the juice obtained by the new process was particularly low in coagulable substances.—J. P. O.

Sugar juice; Clarification [sulphitation and carbonation] of — regarded from the standpoint of colloid chemistry. W. H. T. Harloff. Arch. Suikerind. Nederl.-Indië, 1920, 28, 802–824. Int. Sugar J., 1920, 22, 705–706.

IN order to obtain the maximum adsorption of colloidal impurities from the raw juice by the precipitate produced during the sulphitation method of clarification, the quantity of the precipitate should be as great as economical considerations will permit; precipitation should be effected at as high a temperature as possible without incurring inversion or decomposition, namely about 85° C., in order to obtain a precipitate of good crystalline structure; and precipitation should be rapid. During settling the reaction should be slightly acid, this having been found to be the optimum reaction for the adsorption by the precipitate of gums and pectins, and colouring matters. In the carbonation process, by raising the initial temperature to 55° C., and thus obtaining a more "porous" precipitate of calcium carbonate, 40% less lime can be used. The following conditions for operating single carbonation are recommended: preliminary temperature of the raw juice, 55° C.; alkalinity after carbonating, 200 mg. CaO per l. (phenolphthalein indicator); final temperature of heating, 85° C.

—J. P. O.

Sulphitation method of cane juice clarification; Prevention of incrustation in the heaters used in the —. F. van Vollenhoven. Arch. Suikerind. Nederl.-Indië, 1920, 28, 918–922.

IN Java tubular heaters are used for raising the temperature of the raw juice to 65°–70° C. previous to sulphiting; while another set is employed for heating the juice to boiling point after it has been both sulphited and limed. In order to diminish the formation of scale in the second set of heaters, it is proposed that the two sets be connected together and used alternately for the untreated and the treated juice. This suggestion is based on the fact that sulphite scale is soluble to the extent of about 50% in a dilute solution of sugar.

—J. P. O.

Sulphitation method of cane juice clarification; Prevention of incrustation in the heaters used in the —. G. Benthem. Arch. Suikerind. Nederl.-Indië, 1920, 28, 1040–1042.

SATISFACTORY results may be obtained by the procedure recommended by Vollenhoven (*cf. supra*), but the author prefers to change over from one set of heaters to the other after an interval of, say, 6 hrs., instead of 3–5 days, as originally suggested. In this way the surface of the tubes is kept free from any considerable amount of scale, and a better transmission of heat is secured. A sample of the scale in question gave the following figures: Water (at 135° C.), 9.87; organic matter, 16.20; insoluble in hydrochloric acid, 5.75; P_2O_5 , 0.88; $Al_2O_3 + Fe_2O_3$, 0.54; MgO, 0.37; CaO, 34.51; SO_2 , 2.90; SO_3 , 28.84; and CO_2 and undetermined matter, 0.14%.

—J. P. O.

Sugars; Determination of alkalinity of raw —. G. Bruhns. Zentr. Zuckerind., 1920, 28, 935–936. Chem. Zentr., 1920, 91, IV., 535–536.

MANY raw (beet) sugars, if covered with water containing red phenolphthalein, give at first a yellow solution which becomes red after some time owing to the gradual solution of calcium carbonate contained in the sugar. This behaviour is sometimes shown by juices, syrups, and white sugar. The red colour may eventually vanish owing to absorption of carbon dioxide from the air. In testing the reaction of sugar which is to be stored, such delayed reddening should be neglected, i.e., the sugar should not be returned as alkaline, for solid calcium carbonate affords little protection against acidification and deterioration during storage. If, however, the sugar is to be inverted for the production of syrup or artificial honey, any calcium carbonate present should be reckoned as alkalinity in view of the very small quantity of acid used for inversion. In such cases the alkalinity may be determined by dissolving 20 g. of the sugar in 100 c.c. of water and 5 c.c. of N/10-hydrochloric acid, boiling for 5 mins., cooling, and titrating back with sodium hydroxide.—J. H. L.

Sugars; Volumetric determination of mixtures of —. T. von Fellenberg. Mitt. Lebensmittel. u. Hyg., 1920, 11, 129–153. Chem. Zentr., 1920, 91, IV., 536–537.

THE author uses a modified Fehling's solution containing sodium carbonate as well as sodium hydroxide; 20 c.c. of the solution is boiled with an equal volume of sugar solution, the precipitated cuprous oxide dissolved by addition of concentrated sodium chloride solution containing hydrochloric acid, the solution treated with a slight excess of sodium hydroxide, and the reduced copper determined iodometrically. Tables are given for dextrose, invert sugar, lactose, and maltose in terms of N/10-iodine solution. For the analysis of mixtures of sugars a scheme is given involving one or more of the following processes, viz., "weak inversion,"

in which 50 c.c. of sugar solution is heated with 1 c.c. of *N*/1-hydrochloric acid for ½ hr. in boiling water; "strong inversion," in which 50 c.c. of sugar solution is heated with 25 c.c. of 3*N*-hydrochloric acid for ½ hr. in boiling water; and destruction of reducing sugars by means of sodium hydroxide. For details the original paper should be consulted.—J. H. L.

Sugars; New methods for the volumetric determination of reducing —. A. Ionescu and V. Vărgolici. Bul. Soc. Chim. România, 1920, 2, 38—45. Chem. Zentr., 1920, 91, IV., 536.

REDUCING sugars may be conveniently determined with a solution containing 46 g. of potassium ferricyanide and 46 g. of potassium hydroxide per l. 10 c.c. of this solution, which is stable in the dark, is diluted with 20 c.c. of water, and heated to boiling, and the sugar solution is added from a burette until decolorisation occurs. With coloured liquids 10 drops of 1% picric acid solution are added as indicator, the formation of red picramic acid marking the end-point. 10 c.c. of the ferricyanide solution requires 10 c.c. of 0.5% dextrose solution. For the determination of lactose in milk, 10 c.c. of the latter is mixed with 10 c.c. of a solution containing 20 g. of glacial acetic acid and 10 g. of picric acid per l., and filtered; 10 c.c. of the filtrate is neutralised with sodium hydroxide, diluted to 40 c.c. and employed for the titration as above. 10 c.c. of ferricyanide solution corresponds with 0.0676 g. of lactose.—J. H. L.

Reducing sugars; Determination of —. C. A. Browne. J. Assoc. Off. Agric. Chem., 1919, 3, 261—263.

CRUCIOUS oxide obtained in the gravimetric determination of reducing sugars can be readily reduced to the metallic state by heating the crucible containing it to dull redness and plunging it into the vapour of methyl alcohol (*cf.* Wedderburn, J., 1915, 854). The alcohol used should be changed frequently, since oxidation products present in it may interfere with complete reduction; and there is danger of decomposition of alcohol with deposition of carbon if the crucible is heated to too high a temperature.—J. P. O.

Dextrose; Determination of small quantities of —. Perrier. J. Pharm. Chim., 1920, 22, 337—344.

THE iodometric method described by Bougault (J., 1917, 899) is recommended for the determination of very small quantities of dextrose. The dextrose solution is treated with an excess of *N*/100 iodine solution, 1 c.c. of 1.5% sodium carbonate solution is added for each 25 c.c. of the iodine solution used, and, after 2 hrs.' contact, the mixture is acidified with hydrochloric acid and the excess of iodine titrated with *N*/100 thiosulphate solution; 0.1 c.c. is deducted from the volume of iodine solution used for the actual oxidation and the remainder is calculated into dextrose. The method may be used for the determination of dextrose in body fluids after they have been suitably defecated.—W. P. S.

Copper; Determination of — (especially in sugar analysis) by means of potassium thiocyanate and potassium iodide. G. Brulins. Z. anal. Chem., 1920, 59, 337—359.

THE following procedure is given for determining the amount of unreduced copper when reducing sugars are heated with Fehling's solution. Twenty c.c. of the sugar solution (containing not more than 0.4% of reducing sugar) is mixed with 20 c.c. of Fehling's solution, heated to boiling, and the boiling continued for exactly 2 mins.; 50 c.c. of cold water is added, the mixture is cooled rapidly, 5 c.c. of potassium thiocyanate-iodide solution

(KCNS, 0.65, KI, 0.1 g. per 5 c.c.) is added, followed by 10 c.c. of 6.5*N* sulphuric acid, and the liberated iodine is titrated with thiosulphate solution (34.4 g. per l.). A control titration is made at the same time, using the same quantities of reagents but omitting the boiling operation; the difference in the amounts of thiosulphate solution used for the two titrations is a measure of the reducing sugar present. Tables are given showing the quantities of invert sugar corresponding with different quantities of thiosulphate solution.

—W. P. S.

Molasses; Pycnometer for the determination of the specific gravity of —. W. B. Newkirk, U.S. Bureau of Standards. Technol. Paper No. 161, 1920.

A *WUB* provided with a stop-cock is attached to the pycnometer, and after filling the pycnometer entirely and the bulb partly with the molasses, the apparatus is placed under reduced pressure in order to remove the dissolved gases and entangled air from the molasses; when bubbles no longer collect in the bulb, the pycnometer is disconnected, sealed off, and weighed. Results accurate to a few hundredths of a per cent. of dry substance can be obtained. The use of heat to aid the elimination of the gases causes sufficient decomposition to vitiate the readings.—J. P. O.

Lactose; Solubility of —. J. Gillis. Rec. Trav. Chim., 1920, 39, 677—678.

THE following results have been obtained for the solubility of lactose in water at temperatures above 50° C. The figures represent percentage by weight of lactose ($C_{12}H_{22}O_{11}$) in the solution:—57.1° C., 34.9; 63.9°, 39.1; 73.5°, 45.8; 79.1°, 49.6; 87.2°, 55.1; 88.2°, 56.0; 107.0°, 63.9; 121.5°, 69.4; 133.6°, 73.2; 138.8°, 75.2; 158.8°, 81.1; 178.8° C., 86.7. (*Cf.* Hudson, J., 1908, 1168; Saillard, J., 1919, 919 A)—W. G.

Potato starch manufacture; Chemistry of —. H. Tryller. Chem.-Zeit., 1920, 44, 833—834, 845—847.

ORDINARY potato starch may be considered to be the calcium salt of starch-phosphoric acid, the anhydrous substance having the formula $(C_6H_{10}O_5)_n(OH)PO_3Ca$, where *n* has a value of 260, corresponding with a P_2O_5 content of 0.165%; a part of the calcium is, however, always replaced by magnesium, potassium, iron, and manganese. In the potato itself, the starch is present as the potassium salt, but during the process of preparation the potassium is replaced by calcium derived from the water used for washing the starch. The calcium may also be replaced by heavy metals.—W. P. S.

Sugar-cane wax. Bosz. See XII.

PATENTS.

Sugar manufacture; Horizontal evaporator, especially for —. V. Frynta. G.P. 323,341, 27.3.19. Conv., 11.1.18.

THE evaporator has a liquid chamber at each end, and these are connected by rows of inclined tubes supported at the ends by vertical tube-plates on the outer sides of which horizontal channels are fixed one above another. The liquid on the floor of the chamber covers the lower ends of the bottom row of tubes and extends along them for some distance. When the apparatus is working, this liquid is carried along the tubes by ebullition, and on emerging from their upper ends it falls into one of the horizontal channels. From this it is similarly carried up a higher row of tubes sloping in the

opposite direction. It thus passes from end to end of the tubular system, mounting from channel to channel.—J. H. L.

Oralic acid from sugar. U.S.P. 1,356,137. See XX.

XVIII.—FERMENTATION INDUSTRIES.

Malt; Mashing experiments with a defectively modified —. H. Lüers and M. Schneider. Z. ges. Brauw., 1920, 43, 313—315, 321—324, 329—331.

A VERY badly modified malt, containing 22% of hard and steely corns and 15% of ungerminated corns, was subjected to laboratory mashing tests by 15 different methods. The highest yield from grist of ordinary fineness was 75.62% of the dry substance and was obtained by a combination of cold pre-digestion, proteolytic digestion at 45° C., and mash-boiling.—J. H. L.

Yeast; Influence of temperature on various functions of —. H. Zikes. Zentr. Bakt., 1919, 11., 49, 353; 1920, 50, 385. Z. ges. Brauw., 1920, 43, 211—213, 316—319.

THE author deals with the influence of temperature on the reproduction, sporulation, fermentation, and liquefaction of yeast, on the shape of cells and the production of fat, glycogen, and pigments, on surface films and giant colonies, on the activity of yeast enzymes, and the transformation of bottom-into top-fermentation yeast. The exercise of some of these functions, e.g., reproduction, fermentation, and sporulation, is influenced, at least for a time, by the temperature to which the yeast has previously been accustomed. Production of acid, esters, and fat is more rapid at high temperatures (20°—30° C.) than at low ones (12°—15° C.), whilst the converse applies to the formation of colouring matters by pigment yeasts. Low temperatures favour the formation of elongated cells which remain attached, whilst high temperatures tend to produce round or ovoid cells which separate more readily.—J. H. L.

Acetaldehyde; Formation of — by certain pentose-fermenting bacteria. W. H. Peterson and E. B. Fred. J. Biol. Chem., 1920, 44, 29—46.

WHEN a fixative such as sodium or calcium bisulphite is present in the fermentation mixture, acetaldehyde is formed during fermentation by *Bac. acetothyllicum* (J., 1919, 734 A, 786 A), by *Lactobac. pentoaceticus* (J., 1919, 840 A; 1920, 381 A, 607 A), and by a pentose-fermenting organism isolated from sunflower silage and apparently belonging to the colon-aerogenes group. The formation of acetaldehyde is accompanied by a high proportion of volatile acids in the fermentation products, and the yield of alcohol decreases with increase in the production of aldehyde. (Cf. J.C.S., Dec.)

—J. C. D.

Emulsin enzymes; Resistance of — to the prolonged action of 70% methyl alcohol. M. Bridel. J. Pharm. Chim., 1920, 22, 323—327.

THE activity of the enzymes is decreased, but not destroyed, when the emulsin is kept for 5 years in 70% methyl alcohol; the enzymes which act on lactose and β -ethylgalactoside appear to be more resistant than is that which acts on β -glucosides.

PATENTS.

Glycerol; Manufacture of — from sugar. Verein. Chem. Werke A.-G. E.P. 138,330, 21.1.20. Conv., 19.5.16. Addn. to 138,099 (J., 1920, 608 A.)

A NEUTRAL salt of an alkaline-earth metal or of magnesium or aluminium is added to the fermentation liquid. This renders possible a large increase in the amount of alkaline substance or sulphite added, and consequently an increased yield of glycerol. If 1 kg. of sugar, 500 g. of anhydrous sodium sulphite, and 250 g. of magnesium sulphate are dissolved in 5 l. of water and fermented at 32° C. with 100 g. of yeast, the yield of alcohol obtained is 15% and that of glycerol 33% of the weight of sugar.—J. H. L.

Distillers' slops; Process of treating —. H. P. Basset. U.S.P. 1,357,133, 26.10.20. Appl., 3.11.19. Renewed 10.9.20.

DISTILLERS' slop is subjected to the action of the higher hydroxide of a metal which is capable of forming higher and lower hydroxides and capable also of forming an insoluble basic salt with volatile fatty acids; the hydroxide is maintained in the higher state of oxidation by suitable oxidising treatment, the liquid is acidified, and glycerol is separated from it.—J. H. L.

Medicinal preparations. G.P. 324,747. See XX.

XIXA.—FOODS.

Milk samples; Sour — and Gerber's fat method. F. E. Day. Analyst, 1920, 45, 411—412.

GERBER'S method for the determination of fat in milk yields high results when applied to sour milks, owing to the formation of amyl esters of the lower aliphatic acids. Lactic acid has no effect, acetic acid little, but butyric acid causes a considerable error. The addition of 1% of butyric acid to milk increases the observed fat content by 0.57%; in the case of a sample of milk, 5 weeks old and having a strong odour of butyric acid, the amount of fat found was 0.19% too high.—W. P. S.

Diastase; Occurrence of — in sweet potato in relation to the preparation of sweet potato syrup. H. C. Gore. J. Biol. Chem., 1920, 44, 19—20.

SWEET potatoes possess a high diastatic power, and it is possible to convert nearly all their starch into soluble carbohydrates by slowly cooking the potatoes in water.—J. C. D.

Yeast; Factors which interfere with use of — as a test organism for the antineuritic substance [vitamin B]. G. de P. Souza and E. V. McCollum. J. Biol. Chem., 1920, 44, 113—129.

THE use of yeast (Williams, J., 1919, 692 A; 1920, 608 A) is regarded as unreliable, being subject to many disturbing factors.—J. C. D.

Vitamin; Effect of cooking on water-soluble B— in carrots and navy beans. E. W. Miller. J. Biol. Chem., 1920, 44, 159—173.

ORDINARY cooking processes appear to cause no destruction of the vitamin in carrots, but some loss may occur in the case of navy beans. Much vitamin is found in the cooking water. (Cf. J.C.S., Dec.)—J. C. D.

Vitamin; Water-soluble B — in cabbage and onion. B. K. Whipple. J. Biol. Chem., 1920, 44, 175—187.

THE vitamin in these two vegetables is not destroyed by cooking (boiling), but much may be lost in the cooking water. (Cf. J.C.S., Dec.)—J. C. D.

Reducing sugars. Ionescu and Vărgolici. See XVII.

Solubility of lactose. Gillis. See XVII.

PATENTS.

Pasteurising apparatus. P. I. Buass. E.P. 140,131, 17.3.20. Conv., 17.3.19.

PASTEURISING apparatus of the regenerative type, for milk or other liquid, is provided with means for regulating the regenerative heating of the incoming milk, for preventing mixing of the fresh and pasteurised milk by leakage, and for reading the thermometer from the ground level.—W. F. F.

Buttermilk; Method of drying —. N. P. Collis, Assr. to Collis Products Co. U.S.P. 1,356,310, 19.10.20. Appl., 3.10.19.

BUTTERMILK in which the insoluble curd is maintained in a state of fine suspension by agitation is projected as a spray against a heated surface, on which the soluble and insoluble constituents are deposited, and the deposit is removed and completely dried and disintegrated by mechanical motion through air. (*U.S.P.* 1,317,777; J.L. 1919, 960 A.)—J. H. L.

Cream; Method of and solution for ascertainment of the quantity of fat in —. H. M. Höyberg. U.S.P. 1,357,168, 26.10.20. Appl., 26.1.20.

THE solution claimed contains 50–70 g. of sodium hydroxide and 70–130 g. of sodium potassium tartrate in 1 l. of water. To determine the fat in un-diluted cream, 5 vols. of the latter is mixed with 6.5 vols. of the above solution and 0.16 vol. of isobutyl alcohol in a butyrometer tube, and after the mixture has remained for 15–20 mins. in a water bath at 60°–70° C. the volume of fat is noted.

—J. H. L.

Bread; Type of —. C. O. Johns and A. J. Finks. U.S.P. 1,356,988, 26.10.20. Appl., 4.9.20.

CEREAL flour is mixed with a smaller proportion of soya bean flour and still smaller proportions of table salt, dicalcium phosphate, butter, water, and yeast, and the mixture is kneaded and baked.

—J. H. L.

Eggs; Production of dried yolk or white of —. K. Ebers. G.P. 325,114, 10.1.18.

YOLK or white of eggs, which has been preserved by means of antiseptics, is first freed from the latter by dialysis and then rapidly desiccated in a known manner by atomising in a current of dry or warm air. If antiseptics which are only slightly soluble in water or non-dialysable, e.g., benzoic or boric acid, are present, they may first be converted into dialysable substances, e.g., by addition of alkali.

—J. H. L.

Fodder rich in protein; Manufacture of —. Verein der Spiritus-Fabrikanten in Deutschland. G.P. (A) 325,443, 14.6.18, and (n) 325,444, 27.6.19.

UREA is added to (a) a fodder containing sugar, such as beets or molasses, or (n) carbohydrate fodders in general.—L. A. C.

Bones; Production of fat and protein substances from —. Militärkonserven-Fabr. Abt. Fette, Extrakte und Nebenprodukte Heinemann und Hanka. G.P. 325,755, 14.2.19.

AFTER a preliminary removal of fat by treatment under pressure in autoclaves the bone residues are boiled with a solution of sodium carbonate; the proteins dissolve, the fat floats on the surface, and the mineral matter is deposited.—J. H. L.

Butter making; Process of —. [*Determination of fat in milk and cream.*] H. M. Höyberg. E.P. 153,446, 10.10.19.

SEE U.S.P. 1,329,183 and 1,357,168 of 1920; J.L. 1920, 277 A, and preceding.

XIXB.—WATER PURIFICATION; SANITATION.

Nitrites [in water]; Detection of —. L. Thévenon. J. Pharm. Chim., 1920, 22, 336–347.

TEN c.c. of the nitrite solution is treated with 8 drops of 3% acetic acid and 3 c.c. of 0.5% p-aminophenol solution; a stable red coloration at once develops. The test may be used for the detection of nitrites in water, since the reaction is not given by nitrates, and the salts usually occurring in natural waters do not interfere.—W. P. S.

Air analysis apparatus. Frederick. See XXIII.

PATENTS.

Polysulphides [fungicides]; Method of stabilising — and the products of such method. D. Davidson, and Bradley and Vrooman Co. U.S.P. 1,338,678, 4.5.20. Appl., 6.10.19.

A POLYSULPHIDE in solution is incorporated with a protein substance, such as glue, and the solution is evaporated to yield a solid product consisting of particles of polysulphide encased in glue. The solid product contains 3–15% of glue.

Insecticide. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 324,757, 11.7.19.

AN insecticide is composed of hydro-derivatives of naphthalene, such as α - or β -dihydro- or tetrahydronaphthalene, either alone or mixed with other substances.—J. S. G. T.

Germs, ferments, and toxins; Destruction of —. H. Bechhold. G.P. 325,505, 27.3.18.

Porous materials or powders, which present a large surface, are prepared for use as bactericides etc., by being coated with different metals to promote galvanic action, non-metallic substances being also added if desired. The germs are adsorbed at the surface of the coated material and are destroyed. Whilst bolus coated with silver has little activity when used alone, it greatly increases the activity of bolus coated with copper.—W. J. W.

Centrifugal separator and process [for purifying water]. R. A. Sturgeon. U.S.P. 1,356,665, 26.10.20. Appl., 11.4.19.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Chloropicrin and water; Intersolubility of —. T. G. Thompson and J. H. Black. J. Ind. Eng. Chem., 1920, 12, 1066–1067.

CHLOROPICRIN was emulsified with water and the separating aqueous layers kept at 25° C. for 6 hrs. and the amount of chloropicrin determined as follows: The liquid (100 c.c.) was treated with alcoholic sodium sulphite solution, and then evaporated to 10 c.c. beneath a reflux air condenser to remove alcohol. The residue was diluted to 100 c.c., treated with excess of standard silver nitrate solution and 10 c.c. of nitric acid, boiled and cooled, and the excess of silver nitrate titrated

with ammonium thiocyanate solution. The amount of chlorine was then calculated into the equivalent chloropierin. The results obtained showed that chloropierin is only slightly soluble in water, the solubility decreasing with rise in temperature, whilst water is only slightly soluble in chloropierin, the solubility increasing with the temperature. (*cf.* J.C.S., Jan., 1921).—C. A. M.

Chloropierin; Control experiments in the manufacture of —. I. Effect of varying quantities of lime upon the yield of chloropierin. H. L. Trumbull, G. T. Sehl, W. I. Burt, and S. G. Seaton. *II. Active chlorine in the sludge from the manufacture of chloropierin.* H. L. Trumbull, S. G. Seaton, and H. Durham. *J. Ind. Eng. Chem.*, 1920, 12, 1068—1069.

UNDER conditions closely approximating those used in the manufacturing process, an excess of lime had no influence upon the yield of chloropierin obtained by the interaction of picric acid, lime, and bleaching powder. Iodometric estimation of the active chlorine in a sludge from a plant in which a fairly large excess of bleaching powder had been used to decompose the calcium picrate during the steam distillation showed that very little was retained. Similar results (0.22–0.32%) were obtained with the sludges from 10 other stills.—C. A. M.

$\beta\beta$ -Dichloroethyl sulphide; Solubility of — in petroleum hydrocarbons, and its purification by extraction with these solvents. T. G. Thompson and H. Odeen. *J. Ind. Eng. Chem.*, 1920, 12, 1057—1062.

DICHLOROETHYL sulphide (twice distilled at 13–14 mm.) is soluble in petroleum hydrocarbons at relatively low temperatures, the critical temperature of solubility increasing with the increase in the percentage of the more complex hydrocarbons. The following critical temperatures were observed: With ligroin (portion distilling below 100° C., sp. gr. 1.6677 at 25° C.), 19° C.; with gasoline (40% below 120° C., 90% below 180° C.), 20.4° C.; kerosene (30% below 200° C., 80% below 230° C.), 25.6° C., and railroad light oil (20% below 200° C., 80% below 260° C.), 37° C. Sulphur monochloride is soluble in all proportions, whilst only a small amount of sulphur dissolves in the petroleum hydrocarbons. Chlorinated mustard gas (prepared by the action of sulphur dichloride on dichloroethyl sulphide in carbon tetrachloride) dissolves in all proportions in railroad light oil above 85° C., but its critical solubility temperature is considerably lower than that of dichloroethyl sulphide. Dichloroethyl sulphide may be extracted with hydrocarbons from the crude commercial product at a temperature slightly above the critical solubility temperature, whilst most of the sulphur, together with the tar-like mass will remain undissolved. On then cooling the supernatant solution considerably below the critical temperature, two liquid layers will be formed, the lower of which is mainly a solution of the hydrocarbon in the mustard gas. If the temperature is lowered still further "solid mustard gas" will be precipitated. The upper layer of hydrocarbon solvent will contain all sulphur monochloride present, chlorinated products of dichloroethyl sulphide, and a certain amount of the sulphide. The lower layer will contain dichloroethyl sulphide and a certain amount of the hydrocarbon. By this means it is possible to extract dichloroethyl sulphide on a large scale from commercial mustard gas. Yields of 51–69% were obtained from a crude product containing 71%. —C. A. M.

Mustard gas; Decomposition of and pressure developed by — in steel shell at 60° C. W. A. Felsing, H. Odeen, and C. B. Petersen. *J. Ind. Eng. Chem.*, 1920, 12, 1063—1065.

MUSTARD gas, whether made at 60° C. or by Levin-

stein's process (*cf.* Green, J., 1919, 363 *n*) undergoes slight decomposition in a steel shell at 60° C., sulphur (5–8% of the liquid contents) being deposited. The pressure developed within the shell reaches a maximum at about 2 atm. after about 9 days. The acidity shows a considerable increase, but not sufficient to cause serious corrosion. Preliminary treatment of the mustard gas with gaseous ammonia retards the formation of pressure to a sufficient extent to justify its use in the case of mustard gas which is to be stored for some time in steel shells or containers.—C. A. M.

Mustard gas; Precipitation of sulphur from crude — by means of ammonia. W. A. Felsing and S. B. Arenson. *J. Ind. Eng. Chem.*, 1920, 12, 1065—1066.

THE "free" sulphur retained by mustard gas produced from sulphur monochloride and ethylene may be partly separated by moisture, freezing, and standing for a long time. By treating the product with moist ammonia 40–45% of the sulphur in this form is precipitated. Since its removal does not materially affect the m.p. of the mustard gas, it is probable that this sulphur is present in the colloidal state, whilst the remainder (55–60%) appears to be present in the form of compounds.—C. A. M.

[Organic] acids; Identification of — by phenacyl bromide. [Injurious action of phenacyl bromide on the skin.] H. E. Cox. *Analyst*, 1920, 45, 412.

IN using the method described by Rather and Reid (J., 1919, 199 *A*) care should be taken that the phenacyl bromide does not come into contact with the skin since it produces very painful blisters. —W. P. S.

Amyl alcohol; Catalytic dehydration of fermentation —. J. B. Senderens. *Comptes rend.*, 1920, 171, 916–919.

WHEN fermentation amyl alcohol is dehydrated by passing its vapour over aluminium silicate at 340–350° C., the product consists of a mixture of the three isomeric hydrocarbons, β -methyl- Δ^2 -butylene, β -methyl- Δ^3 -butylene, and γ -methyl- Δ^2 -butylene. If the product is collected in three equal fractions it is found that the relative proportions of these hydrocarbons in the fractions are 704:180:25, 595:238:65, and 302:392:182, respectively. The isomeric change of β -methyl- Δ^2 -butylene into β -methyl- Δ^3 -butylene diminishing as the catalyst decreases in activity.—W. G.

Cineol in eucalyptus oils; Cresineol method for the determination of —. T. T. Cocking. *Perf. Essent. Oil Rec.*, 1920, 11, 362–364.

IN reply to Bennett and Salamon (J., 1920, 704 *A*) the author claims that the phosphoric acid method gives results lower than the true content by amounts varying up to 13%, whereas the results by the cresineol process (J., 1920, 610 *A*) will be only 0–3% low if the non-cineol portion of the oil consists solely of terpene, or 0–3% high if of sesquiterpene. Even in presence of large quantities of other constituents such as esters, which in fact never occur to any appreciable extent in B.P. eucalyptus oils, the maximum error is only 6.3% for a mixture of 2 pts. of cineol with 1 pt. of ester.—G. F. M.

Essential oil of Artemisia annua, L. II. Constitution of artemisia-ketone. Y. Asahina and S. Takagi. *Yakugaku Zasshi* (J. Pharm. Soc., Japan), 1920, No. 464, 837–864.

ARTEMISIA-KETONE isolated from *Artemisia annua* oil (J., 1918 73 *A*) has been found to contain an isomer, and some constants given previously therefore need correction. When oxidised with potassium bichromate and sulphuric acid or concen-

trated nitric acid, tetrahydro-artemisia-ketone yielded acetone (?), acetic acid, and dimethylethyl-acetic acid, whilst artemisia-ketone yielded dimethyl-malonic acid when oxidised with potassium permanganate. By evaporating, *in vacuo*, the mother liquor, from which artemisia-ketone-semicarbazone was isolated, a new ketone was obtained as its semicarbazone compound, m.p. 70° – 72° C. The free ketone, isoartemisia-ketone, $C_{15}H_{24}O$, b.p. 182° – 183° C., sp. gr. 0.8711 at $17^{\circ}/15^{\circ}$ C., n_D^{20} 1.46880, resembles artemisia-ketone in its physical properties, but does not give a semicarbazone. It is converted into tetrahydro-artemisia-ketone when reduced with hydrogen in the presence of platinum-black, and is considered to be an $\alpha\beta$ -unsaturated compound. Artemisia-ketone is converted into the iso-compound by heating with 5% alcoholic sulphuric acid. The content of the iso-ketone in *Artemisia annua* oil is about 10%. The formulae

are given for artemisia-ketone and iso-artemisia-ketone respectively.—K. K.

Sulphur monochloride in mustard gas. Felsing and others. See VII.

PATENTS.

Alcohol or ether; Process and apparatus for the manufacture of—[from ethylene]. A. A. L. J. Damiens, M. C. J. E. de Loisy, and O. J. G. Piette. E.P. 152,495, 16.9.19.

ETHYLENE is absorbed, *e.g.*, from coal gas or coke-oven gas, by sulphuric acid of 66° B. (sp. gr., 1.84) containing one or more catalysts, and the sulphovinic acid formed is decomposed by subsequent distillation after appropriate dilution according to the relative proportions of alcohol and ether desired. Metallic sulphates or sulphuric, phosphoric, phosphorous, or arsenious anhydride may be employed as catalysts; good results are obtained with 1–2% of sulphuric and phosphoric anhydrides, 1–5% of ferrous sulphate, cuprous sulphate, etc. Absorption may be effected in the cold, or preferably at higher temperatures, *e.g.*, 100° – 120° C. Before absorption the ethylene, or gas mixture containing it, is dehydrated and if necessary freed from traces of higher hydrocarbons of the ethylene or acetylene series; and this may be effected by means of acid which has just been saturated with ethylene. The dilute acid from which the alcohol and ether have been distilled may be concentrated again for re-employment as absorbent, by means of gas which has been dehydrated by the process and by means of heat from waste furnace gases. The apparatus comprises a system of purification and absorption columns and distillation plant.—J. H. L.

Solvents [ethyl and methyl chlorides] for extraction purposes. A. Henning. E.P. 152,550, 21.12.19. Addn. to 131,573 (J., 1919, 751 A).

SOLVENTS for the selective extraction of fats, oils, resins, perfumes, etc., consisting of mixtures of ethyl and methyl chlorides, are produced from commercial mixtures of ethyl and methyl alcohols by the process of the chief patent. The mixture of chlorides first obtained may be fractionated to produce on the one hand mixtures relatively rich in methyl chloride, and on the other hand pure ethyl chloride. The use of the solvents for purposes of extraction is also claimed.—J. H. L.

Alkaloids; Process for the selective isolation of—Chem. Fabr. vorm. Sandoz. E.P. 153,219, 16.8.19. Addn. to 125,396 and 131,197 (J., 1920, 349 A, 675 A).

THE crude alkaloidal mixture, *e.g.*, opium, is mixed, if necessary, with previously extracted powdered

vegetable tissue or leaf dust which has been mixed with a concentrated solution of aluminium sulphate; the mixture is then exhausted with benzene, preferably containing up to 10% of alcohol; strongly basic alkaloids, such as morphine, are retained, whilst feebly basic ones, such as narcotine, pass into the extract. The alkaloids in the extract are mixed with more vegetable tissue which has been acidified with sulphuric acid, and the moist powder is exhausted with benzene for the removal of fatty matter. Separation of the alkaloids in each case from the powdered vegetable tissue then follows according to the method described earlier (*loc. cit.*).—D. F. T.

Sodium and potassium formates; Preparation of—Elektrochem. Werke G.m.b.H., and D. Strauss. G.P. 303,894, 1.10.16.

THE solution obtained by decomposing calcium formate with sodium or potassium sulphate, and containing calcium formate and sulphate and alkali sulphate, in addition to alkali formate, is treated with sodium or potassium oxalate and with barium formate. The precipitate formed consists mainly of calcium oxalate with a small quantity of barium sulphate, and may be used for the manufacture of oxalic acid. The solution containing nearly pure alkali formate is evaporated, giving a product suitable for the preparation of alkali oxalate by the known fusion method.—C. A. M.

Oxalic acid; Process of preparation of—[from sugar]. G. H. Gontard and A. Keller, Assrs. to Chemical Foundation, Inc. U.S.P. 1,356,137, 19.10.20. Appl., 30.12.14. Renewed 16.3.20.

SUCROSE (100 pts.) is treated with a mixture of pure sulphuric acid (320 pts.), pure nitric acid (300 pts.), and water (380 pts.) in the presence of a catalyst.—D. F. T.

Salves and emulsions; Bases for—capable of holding a large proportion of water. I. Lifschütz. G.P. 321,012, 17.2.17.

METACHOLESTEROL (G.P. 318,900; J., 1920, 576 A) is mixed or melted with fats or oils. Very pale salves and emulsions can thus be produced possessing great softness and uniformity and a high water-content. Metacholesterol melted with 2% of vaseline is capable of taking up 500% of water.—J. H. L.

Medicinal preparations; Production of—from basic organic dyestuffs and yeast protein. A.-G. vorm. Haaf und Co. G.P. 324,747, 3.4.11.

YEAST protein obtained by liquefying yeast with sodium chloride is coloured with basic organic dyestuffs possessing antiseptic properties, preferably Methyl Violet, Auramines or Safranines, and then heated to about 125° C. by means of superheated steam to fix the dyestuffs and render them inseparable from the protein by washing. The products retain the antiseptic properties of the dyestuffs, and may be used as foodstuffs, disinfectants or for medicinal purposes. That containing Methyl Violet (Pyocetanin) serves for the prevention and treatment of foot-and-mouth disease.—J. H. L.

Benzoic acid; Manufacture of—Commercial Research Co., Asses. of H. W. Walker and V. Coblentz. E.P. 141,333, 19.3.20. Conv., 7.4.19. SEE U.S.P. 1,332,028 of 1920; J., 1920, 291 A.

Mydriatic and process of making same. W. N. Nagai, Assr. to M. D. Bunnell. U.S.P. 1,356,877, 26.10.20. Appl., 1.4.16.

SEE E.P. 120,936 of 1917; J., 1919, 90 A.

Phenolphthalein: Process for preparing combinations of — with carbonates of alkali metal. A. Von Sztankay, Assr. to The Chemical Foundation, Inc. U.S.P. 1,357,482, 2,111,201. Appl., 19.6.14.

Hydrogenation processes. E.P. 152,740. See XII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Panchromatic sensitiveness without dyes; Production of —. J. G. Capstaff and E. R. Bullock. Communication No. 92 from Eastman Kodak Research Laboratory. Brit. J. Phot., 1920, 67, 719—720.

THE fog obtained on the development of some specially treated plates was found to be due to colour-sensitising of the film followed by fogging by the dark-room lamp. The colour-sensitising was produced by a preliminary bathing in a solution of sodium bisulphite and subsequent thorough washing; the degree of sensitising increases with the length of washing up to certain limits dependent on temperature and other conditions. Washing with distilled water is not effective nor is washing with tap water without the preliminary treatment. Addition of alkali to the washing water, or a separate bath of alkali, increases the sensitising effect, and washing in neutral potassium bicarbonate solution is more effective still. Very small quantities of chlorides and bromides in the washing water, but not in the bisulphite bath, reduce the effect. Sensitising is also produced by a preliminary bath of sulphurous acid, but not by one of normal sodium sulphite. The sensitising effect obtained extends to $\gamma=800\mu$.—B. V. S.

Photographic deposits; Measurement of graininess in —. L. A. Jones and N. Deisch. Communication from Eastman Kodak Research Laboratory. Brit. J. Phot., 1920, 67, 689—693, 706—709.

By graininess is meant a visual appearance in a photographic negative or positive of a lack of homogeneity in the silver deposit. It may be due to the size and distribution of the individual particles when viewed under high magnification, to the grouping of the particles in clumps, under small magnification as in projection or enlargement, or to the further agglomeration of the clumps, visible to the unaided eye. The second form is the one chiefly dealt with. An apparatus is described by means of which it is possible to obtain a number to express graininess which is reasonably free from subjective influence. An image of the object under examination is projected by means of a microscope, giving known and adjustable magnification, on to a screen of magnesium carbonate alongside another patch of the screen illuminated by a light of controlled intensity. The two patches are viewed through a mirror, the distance of which can be adjusted until the grainy appearance of the image first disappears. The standard for comparison is a cross-ruled screen, 500 lines to the inch. If D_1 , M_1 are the distance and magnification respectively of the cross-line screen, D_2 , M_2 those of the object, N the ruling of the screen, and E the ruling equivalent to the object, then the graininess being inversely proportional to E is $10^6 M_2 D_1 / N M_1 D_2$, the constant 10^6 being arbitrarily chosen. Graininess generally varies with density; observations are therefore usually made on photometric strips and logs, graininess plotted against density. Graininess also varies with γ , the degree of development, but this has not been fully examined. The shape of the graininess-density curve is constant for a given

batch of emulsion and approximately so for different batches of a given emulsion, but varies greatly with different emulsions. Graininess varies considerably with different developers, although not appreciably with changes of bromide or of temperature for the same developer. Of two pyro developers examined the less alkaline gave the less graininess, while of three quinol-carbonate developers the least alkaline gave the most graininess, but a caustic quinol developer gave still more graininess. As the size of the individual grain is independent of the developer used, graininess cannot be a function of grain-size.—B. V. S.

PATENTS.

X-ray plate holders [and intensifying screens]. Siemens und Halske A.-G. E.P. 143,261, 3.7.17.

AN enhanced intensifying effect, dependent on the emission of secondary radiation by bodies exposed to primary X-rays, is obtained by backing up the sensitive film by a composite screen containing elements of varying atomic weights, the lighter elements being nearer the sensitive film. For example, a screen may consist of 2 or 3 layers of tin foil, a layer of mercurous iodide, and a layer of lead, the tin foil being in contact with the sensitive surface of the plate. The graininess of the ordinary intensifying screen composed of a mineral salt is avoided.—B. V. S.

Silver compounds and products; Process of reducing the [light-] sensitiveness of —. N. Sulzberger. U.S.P. 1,356,236, 19.10.20. Appl., 26.4.15. Renewed 7.9.20.

THE light-sensitiveness of photographic silver compounds is reduced by treatment with a solution of a soluble ferrocyanide.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Trinitrotoluene; Utilisation of — as a blasting explosive. C. E. Munroe and S. P. Howell. U.S. Dept. of Agric., Circular 94, May, 1920, 24 pages.

TESTED with the pendulum friction device and the impact machine, T.N.T. showed less sensitiveness to percussion than straight or gelatin dynamites or picric acid, and it failed to detonate when fired at from a 35-cal. rifle. In the explosion by influence test, at 20° — 23° C., with a No. 6 detonator negative results were obtained at 6 in., and a positive effect was sometimes obtained at 5 in. On the other hand, with a No. 8 detonator, explosion always occurred at 5 in. and sometimes at 6 in. 20% ammonia dynamite was detonated with a No. 6 detonator at 8—9 in. The ballistic pendulum unit defective charges of grades I., II., and III. were 201, 199, and 209 g., that of 40% dynamite being 227 g.; and the propulsive capacities were respectively 113, 114, and 109% of that of 40% dynamite. The velocity of detonation of the three grades, of which the apparent specific gravities were 0.91, 0.88, and 0.86, was 4747, 4852, and 4482 m. per sec., equivalent to 99, 102, and 94% of that of 40% dynamite of apparent sp. gr. 1.24. In the Trauzl block test granulated T.N.T. produced an expansion equal to 113.1% of that given by 40% dynamite. Comparative tests of the three grades of T.N.T. and of 40% straight and ammonia dynamites showed that T.N.T. grade III. is best so far as water-resisting properties are concerned. T.N.T. was successfully detonated with a No. 8 detonator after addition of 10% of water, and with a No. 6 detonator when mixed with 5% of water. As desensitising agents, to prevent detonation of T.N.T. with a No. 8 detonator, 14% of water, or 16% of kieselguhr, or 96% of sodium chloride may be added; and to prevent continuous combustion, 2% of water or 52% of kieselguhr is sufficient. The results of prac-

tical field tests with T.N.T. by the U.S. Bureau of Mines and by the Agricultural College of Wisconsin University indicate that the explosive can be safely used for splitting boulders, removing stumps, and splitting logs, the best effects being obtained with a No. 8 detonator and justifying its increased cost as compared with a No. 6. The amount of T.N.T. required is about 75% of the necessary charge with 20% ammonia dynamite; overloading of improperly cartridge material may prove dangerous. Moisture does not materially affect the work, and grade III. will detonate completely even under water, so that the removal of stumps may be carried out in the wet season, when the soft ground facilitates the boring of holes and the working cost is therefore considerably reduced. For most purposes grade III. is found to be most suitable. The health of the workers is not noticeably affected in open-air work.—W. J. W.

Trinitrotoluene; Products of detonation of —. C. E. Munroe and S. P. Howell. Proc. Amer. Phil. Soc., 1920, 59, 191—223. (Reprint.)

THE trinitrotoluene used had solidif. p. 80.2° C., and nitrogen content 18.32% as determined by Dumas' method, or 18.14% as found by a modification of the Kjeldahl method. A Bichel pressure gauge was used, the charges being wrapped in tin-foil and exploded with a No. 8 detonator, and the detonation products were analysed in Burrell's modification of the Orsat apparatus (J. Ind. Eng. Chem., 1916, 8, 228—231). From ten experiments with trinitrotoluene charges of 25, 50, 75, 100, 150, 200, 250, 300, 350, and 450 g., with loading densities increasing from 0.0016 to 0.003, the maximum and minimum amounts of gaseous products were as follows:—CO₂, 6.4, 1.1%; CO, 60.7, 53.2%; H₂, 27.6, 19.9%; CH₄, 2.3, 0.1%; N₂, 15.6, 13.3%. An odour of ammonia was detected in every case; its estimation in a single experiment gave 0.031. Two experiments with trinitrotoluene of density 0.86 and 1.50 respectively showed that the density causes no alteration in the detonation products. Solid combustion products were found in the gauge after the experiments, the amounts from three 200 g. charges being 5.5, 8.0, and 9.25%, and from a 400 g. charge 3.75 g. The amount of solid matter appears to decrease with the weight of the charge and to increase with its density. The composition after eliminating contaminating substances was:—H, 1.03%; C, 96.07%; N, 2.90%. A determination of the gases absorbed by the solid products indicated 6.11 c.c. per g.; the composition of the absorbed gas was CO₂, 71.3%; CH₄, 1.0; N₂, 27.7%. The amount absorbed is too small to affect the analysis of the gaseous detonation products.—W. J. W.

Mercuric azide; Preparation and properties of —. A. Stettbacher. Z. ges. Schiess- u. Sprengstoffw., 1920, 15, 211—212.

THE extraordinary sensitiveness of mercuric azide prohibits its manufacture and employment commercially, but it may be prepared with comparative safety on a laboratory scale if stringent precautions are adopted. A solution of 6.5 g. of sodium azide is decomposed with concentrated sulphuric acid, and the gaseous hydrogen nitride is passed into 10 g. of mercuric oxide in 200 c.c. of boiling water. The hot mercuric azide solution produced is passed through a filter provided with a hot-water jacket, and the filtrate is gently stirred with a wooden splinter during cooling to prevent formation of crystals longer than 1 mm., which are extremely sensitive even under water, and to secure the azide as a crystalline mass in which state it is not appreciably more sensitive than silver fulminate. Great care is demanded in the handling of the filter and funnel after filtration on account of possible deposition of needle crystals. Mercuric azide may

also be produced as a powdery mass of less sensitiveness than lead azide by mixing solutions of sodium azide and mercuric nitrate. The sensitive form may be produced from this variety by solution and crystallisation. Although mercuric azide has the same molecular weight as mercuric fulminate, and develops an equal volume of gas on detonation, its brisance is about 20—30 times as great.—W. J. W.

Smokeless powders; Determination of mineral residue in —. C. Lutri. Giorn. Chim. Ind. Appl., 1920, 2, 214—216.

FIVE g. of the finely divided powder is treated with about 8 g. of pyridine in a beaker which is immersed at intervals in a water bath. After 48 hrs. the material will have been converted into a mobile liquid; the contents of the beaker are treated with 20 c.c. of alcohol and filtered through a Gooch crucible, and the residue washed with alcohol, ether, hot benzene, dilute hydrochloric acid, and water, and then ignited to incipient incandescence and weighed. The method is also suitable for the determination of graphite in smokeless powders.

—C. A. M.

Hexanitrodiphenyl; Sensitiveness of — to mechanical shock as compared with that of hexanitro-compounds of similar constitution. C. F. van Duin. Rec. Trav. Chim., 1920, 39, 685—688. (Cf. J., 1919, 697 A; 1920, 676 A.)

HEXANITRODIPHENYL is more sensitive to mechanical shock than trinitrobenzene, but is much less sensitive than trinitrophenylmethylamine and hexanitrodiphenyl oxide and sulphide.—W. G.

PATENTS.

Propellant powder, and process of making same. C. I. B. Henning, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,357,865, 2.11.20. Appl., 3.3.20.

AN oxygen derivative of a metal capable of reducing fouling is added in a finely-divided condition to a propellant powder.—W. J. W.

Detonating agent for shells, mines, and detonators. Westfälisch-Anhaltische Sprengstoff A.-G. G.P. 291,830, 20.4.15.

DINITROALKYLOXAMIDES, especially dinitrodimethyl-oxamide, may be used as detonating agents. Dinitrodimethyl-oxamide is a white substance, which does not attack the skin, and is not toxic. It gives a lead block expansion equal to that of picric acid, but is less sensitive to shock than the latter, and also than aliphatic nitric esters, such as gun cotton.—W. J. W.

Smokeless powder; Manufacture of —. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 300,635, 14.9.16.

TO increase the stability, and reduce the ignition temperature of nitrocellulose, or nitrocellulose and nitroglycerin powders, alkylarylexanamides or diarylexanamides, such as methylphenylexanamide or diphenylexanamide, are added.—W. J. W.

Smokeless powders; Treatment of —. Claessen. G.P. 300,726, 25.4.17.

SMOKELESS powder is treated superficially with a fusible, aromatic nitro-compound in order to promote progressive combustion and to control the gas pressure.—W. J. W.

Nitration of webs of cellulose; Process for the —. T. Niederländer. G. P. 300,749, 14.5.16.

THE cellulose (e.g., paper) is passed through the nitration bath by means of mechanically operated suction rollers, whereby the nitration acid is drawn through the cellulose. To avoid decomposition of the nitrocellulose after nitration, a water spray is

employed during the subsequent operations (pressing etc.) preceding pulping.—W. J. W.

Compressed explosive charges; Production of —. von Schrötter. G.P. 304,299, 9.11.17.

THE sensitiveness of explosive charges may be reduced by melting the explosive, and then breaking it up into large fragments before pressing.

—W. J. W.

Explosive for military purposes; Manufacture of an —. Deutsche Sprengstoff A.-G. G.P. 325,612, 23.4.18.

NITROCELLULOSE is mixed under water with insoluble nitrohydrocarbons, such as trinitrotoluene or trinitronaphthalene, and the wet mixture is then compressed. The finished charges can be detonated either in a wet or dry state.—W. J. W.

Incendiary compositions; Manufacture of —. Oberschlesische Sprengstoff A.-G. G.P. (A) 302,420, 10.8.16, and (B) 302,600, 12.9.16.

(A) An incendiary composition consists of nitrocellulose dissolved in a combustible solvent which may have an oxygen-carrier in suspension. (B) To ensure rapid and safe ignition with an enhanced effect, a mixture of perchlorate, nitrohydrocarbon, and wood meal may be incorporated with the material.—W. J. W.

Fireworks composition; Manufacture of —. E. Bock. G.P. 304,356, 29.10.16.

IN fireworks composition, such as Bengal lights, charred woodmeal or sawdust may be substituted for sulphur, resin, shellac, etc.—W. J. W.

XXIII.—ANALYSIS.

Litmus paper; Treatment of red —. T. J. Ward. Analyst, 1920, 45, 412—413.

RED litmus paper, as bought, is not readily wetted by aqueous solutions owing to the sizing of the original paper with rosin. The latter may be removed by immersing the books of papers for some hours in alcohol containing 1% of concentrated hydrochloric acid and then extracting them with alcohol in a Soxhlet apparatus until no more red colouring matter is removed. The books are then dried at 100° C. Some of the red colouring matter of the litmus is extracted in addition to the rosin.

—W. P. S.

Air analysis apparatus; Improvement in the Haldane general —. R. C. Frederick. Analyst, 1920, 45, 409—410.

THE combustion chamber of the apparatus is made $\frac{3}{4}$ in. shorter than usual, the stem $1\frac{1}{8}$ in. longer, and the mark on the stem is placed $\frac{1}{2}$ in. above the shoulder. These modifications prevent, to some extent, the obscuration of the graduation by the products of combustion, and frequent cleaning is not required. Further, the removal of drops of mercury collecting in the bore of the inlet tap is rendered easier.—W. P. S.

Prism-hardness [of metals etc.]. B. P. Haigh. J. Inst. Mech. Eng., 1920, 891—913.

TEST pieces, preferably square prisms, of the same materials are used to indent one another, when placed cross-wise, and consistent hardness values are obtained by dividing the applied loads by the square of any characteristic linear dimension of the depression produced; measurement of the width gives the greater accuracy, but the depth is more easily measured. In the tests carried out the prism

hardness, P.H., was calculated from the formula $P.H. = P/x^2$, where P is the load and x the width of the indentation from corner to corner along the cutting edge. Among the metals and alloys tested were copper, annealed and hard drawn; naval brass; delta metals; pearlitic steels with 0.18 and 0.43% C, forged, water quenched, water quenched and tempered, and oil quenched; spring steel; austenitic manganese steel; and martensitic steel. Consistent results were obtained, the test being sensitive to slight differences of hardness even in the hardest metals. The scale of hardness given by this test is equally applicable to the hardest and softest metals.—J. W. D.

Hardness; Measurement of high degrees of —. J. Innes. J. Inst. Mech. Eng., 1920, 915—932.

THE hardness (H) of a material depends on the elastic properties, and the following formula is given as a means of determining and measuring it:—

$$H = \frac{\pi^2}{.96} \cdot \frac{(3+4N)^2(3+N)}{N^3} \cdot \frac{Q^3}{C^3}$$

where N is the ratio of modulus of change of size to modulus of change of shape, C the modulus of change of shape, and Q the limiting shear stress. Those three factors can readily be determined separately, and if test pieces of moderate size (rods of 0.1 in. diam. and 3 in. long) are available, two of those constants, C and N, may be measured with almost any desired degree of accuracy. Q is more difficult to measure, especially with brittle materials.—J. W. D.

Hardness testing. H. S. and J. S. G. Primrose. J. Inst. Mech. Eng., 1920, 933—954.

Two new types of testing machines are described, the elastic column dynamometer and a hardness machine with a pendulum dynamometer. In the first type use is made of the principle of the elastic deformation of three sufficiently strong steel columns to measure the load applied to the test piece. This deformation is magnified and measured by means of a mercury calibrating box. The load is applied by a 5-ton screw press. The general arrangement of the method is described, and also a simple form of depth indicator, by means of which the depth of the ball or cone imprint made in the test piece while still in the machine can be measured accurately to 0.01 mm. In the second type of testing machine a depth indicator is used for accurately reading the depth of the imprint; the load is applied by means of an oil-operated hydraulic press, the load indications of which can be varied in four degrees of sensitiveness up to 5 tons, and the load applied is measured by means of a pendulum dynamometer. Tables are given showing comparisons between hardness values obtained with different steels tested by the different methods.—J. W. D.

Immersion refractometer; Use of the — for determining the concentration of aqueous and alcoholic solutions. B. Wagner. Z. angew. Chem., 1920, 33, 262—264.

THE immersion refractometer is recommended as a means for the simple and accurate estimation of the concentrations of solutions, for the preparation and checking of standard solutions, and for the estimation of purity of reagents. Readings of 0.1, or even 0.05, of a scale division can be made with accuracy. Before use the instrument should be checked with distilled water at 17.5° C., the beakers containing the solutions under examination being placed simultaneously in the bath. If the scale reads 15 after an interval of 2 to 3 mins., it may be assumed that the solutions have attained the cor-

rect temperature, but this is preferably checked by a thermometer. Differences of temperature of the prism and of the solutions will be indicated by a blurred or double line. In practice, single readings of the instrument are insufficient; they should be supplemented by readings of 15 to 20 dilutions of the solution. In the compilation of refractometer tables, average values must not be given, as equal increases in the concentration do not correspond to equal increments on the scale. Thus sodium chloride concentrations of 5, 10, 15, and 20° give readings of 37.2, 58.5, 79.2 and 99.5, which, taking water as 15, correspond to 22.2, 21.3, 20.7, and 20.3 scale divisions. When results of analysis of reagents are quoted, it is desirable to quote the refractometer value and the specific gravity, in addition to the percentage purity.—W. J. W.

Acid and basic functions; Indication of the — and their estimation. I. M. Kolthoff. *Rec. Trav. Chim.*, 1920, 39, 672—676.

The acidic or basic nature of a substance may be ascertained by determining the H-ion or OH-ion concentration colorimetrically by the method of indicators after the addition of a known amount (insufficient for neutralisation) of strong acid or base, as the case may be. For determining the quantity of acidic or basic group present, the conductivity titration method (J., 1920, 529 A, 558 A, 735 A) is recommended.—W. G.

Sulphuric acid; Gravimetric determination of — in presence of calcium, phosphoric acid, and chromium. L. W. Winkler. *Z. angew. Chem.*, 1920, 33, 287—288.

To prevent precipitation of a small amount of calcium as sulphate the substance is dissolved in 25 c.c. of 10% hydrochloric acid containing 0.5 g. of ammonium chloride, and 5 c.c. of 10% barium chloride added, drop by drop, to the boiling solution. The liquid is then diluted with 100 c.c. of water, again boiled, and filtered next day. The error due to precipitation of phosphoric acid as barium phosphate is also largely eliminated by the same method. In the presence of 0.05—0.5 g. of phosphoric acid the weight of the dried precipitate (0.3—0.05 g.) should be reduced by 1.1 mg., or that of the ignited precipitate increased by the same amount. Sulphuric acid is only incompletely precipitated from a solution of chromium sulphate, but the remainder may be separated by evaporating the filtrate and washings to dryness, treating the residue with hot water and a few drops of hydrochloric acid, and adding the amount of the precipitate to that of the first precipitate.—C. A. M.

Titanium and iron; Determination of — in rocks. F. Ferrari. *Giorn. Chim. Ind. Appl.*, 1920, 2, 497—498.

For the simultaneous determination of titanium and iron in rocks, an aliquot part of the filtrate from the silica, containing the iron in the ferric condition, is reduced by means of zinc, while a current of carbon dioxide is passed through the flask, and the titanium is titrated with Methylene Blue. Another portion of the filtrate is then titrated with titanous chloride, using potassium thiocyanate as indicator, to obtain the amount of ferric iron.

—C. A. M.

Lead; Determination of small quantities of — [in ores etc.]. J. H. Hastings. *Eng. and Min. J.*, 1920, 110, 867—868.

Is the titration of small quantities of lead sulphate in ammonium acetate solution, with ammonium molybdate solution, using tannin solution as indicator (Alexander; J., 1893, 376), the end-point is indefinite owing to the slowness of the reaction between the molybdate and the lead. This may be

overcome by adding a definite amount of standard lead solution to the test solution before the lead is titrated, allowance being made subsequently for the amount of the added lead.—W. P. S.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- Armstrong. Process of making liquid fuel. 34,843. Dec. 10. (Austria, 16.2.14.)
 Bates. Production of fuel. 34,824. Dec. 9. (U.S., 10.12.19.)
 Boberg, and Techno-Chemical Laboratories, Ltd. Preparation of lignite. 34,207. Dec. 3.
 Bottomley, Weeks, and Merz and McLellan. Production of steam for carbonising plant for large-scale power production. 34,261. Dec. 3.
 Bottomley, Weeks, and Merz and McLellan. Low-temperature distillation of fuel. 34,262. Dec. 3.
 British Thomson-Houston Co. (General Electric Co.). Manufacture of carbon. 34,126. Dec. 2.
 Broadbridge, Jones, and Stenning. Production of coal briquettes. 34,339. Dec. 4.
 Cleary. Manufacture of combustible gas from liquid fuel. 23,645. Nov. 29.
 Duckham, Morgan, and Thermal Industrial and Chemical Research Co. Heating liquids by introduction into molten metal. 34,732. Dec. 8.
 Edser and Vautin. Drying coal etc. concentrates. 34,002. Dec. 1.
 Fleischer. Manufacture of coal distillation products. 34,590. Dec. 7. (Ger., 8.12.16.)
 Fonblanque and Moellar. Manufacture of gas from carbonaceous materials. 33,708. Nov. 30.
 Fonblanque and Moellar. Retorts for low-temperature carbonisation. 33,709. Nov. 30.
 Foster. 34,545. *See* VII.
 Fyeman. Separating asphaltum, bitumen, tar, etc., from mineral matter. 33,983. Dec. 1.
 Helps. Gas manufacture. 34,874-5. Dec. 10.
 Hughes. Gas-generators or producers. 35,012. Dec. 11.
 Knibbs. Distillation of solid hydrocarbon-containing materials. 34,555. Dec. 7.
 Koppers. Gas producers. 33,674. Nov. 29.
 Koppers. Regenerative retort settings. 33,675. Nov. 29.
 Koppers. Coke manufacture. 34,346. Dec. 4.
 Koppers. Ovens for producing gas and coke. 34,429. Dec. 6.

- Lamplough, and Townsmead Construction Co. Manufacture of coal etc. briquettes. 34,396. Dec. 6.
 McTier and Meddleycutt. Neutralising coal dust in mines. 34,235. Dec. 3.
 Persch. Treating petroleum etc. 34,419. Dec. 6.
 Rigby. Treatment of peat. 33,864 and 34,147. Dec. 1 and 3.
 Rigby. Manufacture of briquettes. 33,865. Dec. 1.
 Rigby. Drying peat etc. 34,473. Dec. 7.
 Seccombe. Artificial fuel. 34,151. Dec. 3.
 Thomas and Williams. Appliance for converting pressure produced by reaction of water and calcium carbide into work etc. 33,904. Dec. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

- 15,324 (1919). Underfeed Stoker Co., and McEwen. Carbonisation or destructive distillation. (154,253.) Dec. 8.
 17,777 (1919). Ryan. Recovery of bitumens from shale etc. (129,992.) Dec. 15.
 18,837 (1919). Bussey. Apparatus for treating carbonaceous materials. (154,658.) Dec. 15.
 20,277 (1919). Macdonald, and Densified Peat Fuel and Products, Ltd. Composition fuel. (154,289.) Dec. 8.
 20,735 (1919). Leadbetter. Manufacture of artificial fuel. (154,319.) Dec. 8.
 21,573 (1919). Jackson (Metals Recovery Co.). Concentration of bituminous coal by flotation. (154,702.) Dec. 15.

 28,294 (1919). Bloomfield and Morgan. Suction gas producer. (154,436.) Dec. 8.
 31,073 (1919). Underfeed Stoker Co., and McEwen. Carbonising finely-subdivided fuel. (154,458.) Dec. 8.
 32,019 (1919). Knibbs. Treatment of hydrocarbon oil. (154,464.) Dec. 8.
 2827 (1920). Ellis. *See* I.
 8796 (1920). U.S. Industrial Alcohol Co. Liquid fuels. (140,796.) Dec. 15.
 28,995 (1920). Marks (U.S. Industrial Alcohol Co.). Non-freezing fuel. (154,867.) Dec. 15.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

- Atack. Oxidation of hydrocarbons. 34,274. Dec. 4.
 Fyeman. 33,983. *See* II.
 Kagan. Separating and purifying anthracene and carbazole. 34,733. Dec. 8.
 Scheibler. Manufacture of sulphur preparations of the thiophene series. 35,014. Dec. 11. (Ger., 28.4.14.)

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

- British Dyestuffs Corp., Clemo, and Perkin. Manufacture of basic blue colouring matters. 33,837. Nov. 30.
 British Dyestuffs Corp., Clemo, and Perkin. Manufacture of colouring matters. 33,970. Dec. 1.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Bostock. Rendering paper translucent and durable. 34,845. Dec. 10.
 Dreyfus. Manufacture of solutions, compositions, etc., having a basis of cellulose acetate etc. 33,948. Dec. 1.
 Gassmann. Manufacture of durable masses from viscose. 34,840. Dec. 9. (Ger., 12.12.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 20,675 (1919). Burby. Process of re-working old paper. (151,670.) Dec. 15.
 20,975 (1919). Dreyfus. Manufacture of compositions etc. having a basis of cellulose acetate. (151,311.) Dec. 8.
 21,527 (1919). Drews and Noorden. Treatment of manufactured fabrics to reclaim the fibres. (151,315.) Dec. 8.
 22,146 (1919). Jennison and Chanaz. Paper manufacture. (151,366.) Dec. 8.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

- Hodson. Process of bleaching textile fabrics and materials. 31,965. Dec. 11.
 Leek, and Leek and Sons. Dyeing, bleaching, tin-weighting, scouring, etc. machines. 31,612. Dec. 8.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- Bergdahl. Production of ammonia. 31,715. Dec. 8.
 Casalo and Leprestre. Apparatus for catalytic synthesis of ammonia. 31,124. Dec. 2.
 Casale and Leprestre. Production of nitrogen or mixtures of nitrogen and hydrogen. 31,582. Dec. 7.
 Dunningham and Hargreaves. Manufacture of sodium thiosulphate. 33,958. Dec. 1.
 Fabr. de Prod. Chim. de Thann et de Mulhouse. Manufacture of anhydrous zinc sulphide. 35,008. Dec. 11. (Fr., 16,12,19.)
 Foster. Preparing lime from limestone, and manufacture of power gas and ammonia. 34,545. Dec. 7.
 Harding and Jones. Production of sodium pentaborate, borax, or boric acid from boron ores. 34,193. Dec. 3.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,695 (1919). Cataldi. Electrolytic decomposition of chlorides. (127,255.) Dec. 15.
 20,574 (1919). British Cellulose and Chemical Manuf. Co., Soller, and Hotz. Manufacture of acetic acid. (151,304.) Dec. 8.
 20,931 (1919). Wilton. Manufacture of sulphate of ammonia. (151,328.) Dec. 8.
 21,140 (1919). Dreyfus. Manufacture of acetic acid. (154,680.) Dec. 15.
 21,690 (1919). Island. Fixation of atmospheric nitrogen. (151,356.) Dec. 8.
 22,166 (1919). Matheson. Apparatus for manufacture of acetic acid. (151,368.) Dec. 8.
 32,853 (1919). Heberlein. Electrolysis of nickel salt solution. (151,471.) Dec. 8.
 309 (1920). Datta. Production of potassium and sodium bichromates and sulphates. (151,810.) Dec. 15.
 433 (1920). Napp (Tschudi). Manufacture of hydrobromic acid. (151,472.) Dec. 8.
 4695 (1920). Diehl. *See X.*
 6366 (1920). Lamm. Manufacture of potassium and sodium carbonates. (154,498.) Dec. 8.

IX.—BUILDING MATERIALS.

APPLICATIONS.

- Alletson. Kilns for burning blue bricks. 31,576. Dec. 10.
 Earle. Hydraulic cement. 31,077. Dec. 2.
 Hensman. Treatment of timber with fluid. 33,704. Nov. 29.

- Winkler. Making mortar, cement, etc. 33,633. Nov. 29.

COMPLETE SPECIFICATIONS ACCEPTED.

- 5385 (1918). Friedrich. Producing a cold glaze on building materials, particularly cement. (151,236.) Dec. 8.
 9256 (1920). Simon. Reducing or softening the colours of exotic woods. (141,052.) Dec. 15.
 12,827 (1920). Bakema. Shaft furnaces especially for making cement. (154,510.) Dec. 8.

X.—METALS; METALLURGY. INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

- Andrews. Process for rust-proofing metal. 31,102. Dec. 2.
 Ballantine, Stig, and Stig. Refining ferro-alloys. 31,005. Dec. 1.
 Ballantine, Stig, and Stig. Production of ferro-alloys. 31,006. Dec. 1.
 Chappell and Cowing. Manufacture of nickel steel. 31,140. Dec. 2. (U.S., 16,6,20.)
 Costar, and Enamelled Wires, Ltd. Enamelling or coating wire. 31,162. Dec. 3.
 Evans and Hamilton. Manufacture of steel and alloy steels. 31,294. Dec. 1.
 Ges. f. Wolfram-Industrie. Alloy for wire-drawing dies etc. 31,575. Dec. 7. (Ger., 23,1,18.)
 Groff. Electroplating metallic bodies. 33,966. Dec. 1.
 Miller. Method of enamelling metals. 33,748. Nov. 30.
 Minerals Separation, Ltd., and Simpson. Concentration of ores containing sulphur. 31,141. Dec. 2.
 Moa Iron and Development Corp. Treating ores etc. 33,818. Nov. 30. (U.S., 8,12,19.)
 Raffo. Manufacture of iron and steel. 31,125. Dec. 2.
 Wickett. Electrical treatment of ferrous metals during casting. 31,265. Dec. 3.
 Wood. Flux and solder. 34,608. Dec. 8.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,969 (1918). Garred. Combustion processes and apparatus for smelting ores, melting metals, etc. (151,210.) Dec. 8.
 4838 (1919). Adam, Stevenson, and Mabbitt. Detining of tinned iron scrap. (154,242.) Dec. 8.
 18,337 (1919). Wiberg. Reduction of ores etc. (130,334.) Dec. 8.
 18,868 (1919). McConnell. Manufacture of electric steels. (154,659.) Dec. 15.
 21,691 (1919). Wickett. Electrical treatment of ferrous metals during casting. (154,711.) Dec. 15.
 21,819 (1919). Mackay. Treatment of sulphide ores containing lead and zinc. (151,718.) Dec. 15.
 22,376 and 29,817 (1919). Coles. Production of spring or tempered copper. (154,373.) Dec. 8.
 32,831 (1919). British Thomson-Houston Co. (General Electric Co.). Method of coating metals. (154,808.) Dec. 15.
 4695 (1920). Diehl. Arrangement for blowing air through blast-furnace slag, particularly for recovering the sulphur as sulphur dioxide. (139,173.) Dec. 8.
 22,568 (1920). Russell, and Manchester Furnaces, Ltd. Furnaces for heat-treating. (154,521.) Dec. 8.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

- Groff. 33,966. *See X.*
 Metropolitan-Vickers Electrical Co. Electrolytes for electrolytic cells. 31,117. Dec. 2. (U.S., 9,12,19.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 4948 (1919). Adam, Stevenson, Mabbitt, and Fieldhouse. Electrolysis. (154,635.) Dec. 15.
 12,695 (1919). Cataldi. *See* VII.

 21,334 (1919). Royston (Federal Storage Battery Co.). Electric storage batteries. (154,343.) Dec. 8.
 22,787 (1919). Oldham, Oldham, and Oldham. Galvanic batteries. (154,737.) Dec. 15.
 29,114 (1919). Erichsen. Electric furnaces. (151,444.) Dec. 8.
 32,853 (1919). Heberlein. *See* VII.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

- Dalley. Machine for expressing oil. 34,170. Dec. 3.
 Distillates, Ltd., and Jarman. Treatment of solid residues containing grease. 33,609. Nov. 29.
 Ham and Jarrett. Soap powder and process for preparing same. 34,805. Dec. 9.
 Schueler. Extraction of oil from seeds, nuts, etc., by means of solvent. 34,853. Dec. 10.
 Tseng. Manufacture of soap. 34,831. Dec. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

- 1126 (1920). Nordiske Fabr. De-No-Fa. Catalysts for use in hydrogenating unsaturated organic compounds. (140,371.) Dec. 15.
 10,934 (1920). Townsend. Detergent. (154,843.) Dec. 15.
 14,623 (1920). Vakil. Apparatus for refining oils and fats. (154,514.) Dec. 8.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

- Fabr. de Prod. Chim. de Thann et de Mulhouse. 35,008. *See* VII.
 Kulas and Pauling. Manufacture of resinous condensation products from phenol. 33,875. Dec. 1. (Ger., 23.2.20.)
 Nosawa. Paint for ships' bottoms. 34,722. Dec. 8.
 Shimozaki. Copying-inks. 34,439. Dec. 6.
 Whalley. Recovery of varnish etc. from waste micanite etc. 33,696. Nov. 29.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,002 (1918). Soc. Anon. l'Helice Integrale. Processes of lacquering. (118,616.) Dec. 8.
 18,827 and 31,391 (1919). Vickers, Ltd., Ioco Rubber and Waterproofing Co., and Nuttall. Condensation products of phenolic bodies with aldehydic compounds. (154,656.) Dec. 15.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

- Bilbrough. Rubber compounds and process of manufacture. 33,793. Nov. 30.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

- Carmichael and Ockleston. Treatment of hides and skins. 34,481. Dec. 7.
 Maries. 34,561. *See* XIX.
 Turner. Preparation for treating leather. 34,228. Dec. 3.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

- Blichfeldt and Grove. Saccharification of starchy materials. 34,139. Dec. 2.
 Delafond. Manufacture of sugar direct from juice. 34,457. Dec. 6.
 Dutt and Dutt. Decolorising and purifying saccharine solutions. 34,413. Dec. 6.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

- Fitzgerald. Production of commercial products from blood. 33,637. Nov. 29.
 Hartley and Hartley. Purification of sewage. 34,485. Dec. 7.
 Luft. Food products. 34,026. Dec. 2.
 Maries. Manufacture of solid plastic material from casein. 34,561. Dec. 7.
 Martin and others. Manufacture of condensed milk. 34,709 and 34,710. Dec. 8.
 Martin and others. Manufacture of milk powder. 34,711. Dec. 8.
 Standen. Insecticide. 34,788-9. Dec. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

- 10,457 (1917). Monhaupt. Manufacture of a colloidal solution neutral to the taste from casein and vegetable albumen including gluten. (154,627.) Dec. 15.
 13,087 (1919). Greville. Treatment of flour. (154,639.) Dec. 15.
 13,492-3 (1919). Pique, and Imperial Trust. Cooling and freezing fish etc. (154,250.) Dec. 8.
 19,825 (1919). Lendrich. Manufacture of coffee substitutes. (131,304.) Dec. 8.
 20,667 (1919). Hardy, Pique, and Imperial Trust. Cooling and freezing fish etc. (154,669.) Dec. 15.
 22,349 (1919). Adams. Separating semi-solids from sewage etc. (154,370.) Dec. 8.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

- Henning. Non-inflammable volatile liquid. 34,814. Dec. 9.
 Meister, Lucius, u. Brüning. Manufacture of derivatives 3,3'-diamino-4,4'-dioxarsenobenzene. 33,848. Nov. 30. (Ger., 12.12.19.)
 Meister, Lucius, u. Brüning. Manufacture of esters of dioxidiethyl sulphide. 34,231. Dec. 3. (Ger., 20.1.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 1126 (1920). Nordiske Fabr. De-No-Fa. *See* XII.
 17,860 (1920). Tweedale and Tweedale. Manufacture of perfumery and flavouring essences, extracts, etc. (154,517.) Dec. 8.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

- Dye Impression Photos., Ltd., and Edridge. Photographic films. 34,810. Dec. 9.

XXII.—EXPLOSIVES; MATCHES.

APPLICATION.

- Rathsburg. Manufacture of explosives and primers. 34,241. Dec. 3. (Ger., 3.2.20.)

BY-LAWS OF THE SOCIETY OF CHEMICAL INDUSTRY.

INCORPORATED BY ROYAL CHARTER 17th day of June, 1907.

BY-LAWS

To be submitted for adoption at the Annual General Meeting to be held on 13th July, 1920.

PART I.—PRELIMINARY.

Short Title and Commencement.

(1.) These By-laws made pursuant to the Charter may be cited as "Society of Chemical Industry By-laws, 1920," and shall come into operation so soon as they may be allowed by the Lords of His Majesty's Most Honourable Privy Council.

By-laws divided into parts.

(2.) These By-laws are divided into parts as follows:—

- Part I.—Preliminary.
- Part II.—Members.
- Part III.—The Council.
- Part IV.—Local Sections.
- Part V.—Subject Groups.
- Part VI.—The Journal.
- Part VII.—Financial.
- Part VIII.—Meetings.
- Part IX.—Miscellaneous.

Interpretation.

(3.) In and for the purposes of these By-laws terms and words and expressions to which meanings are assigned by the Charter or the Act made applicable thereto have the same respective meanings, unless there be something in the subject or context repugnant to such construction.

"The Charter" means the Charter granted the 17th day of June, 1907, as amended or extended by supplemental or additional Charters granted to and accepted by the Society after the date aforesaid.

"By-laws" means any By-law of the Society made and allowed pursuant to the Charter.

"Committee" means any Committee duly appointed by the Council, and where qualified by any prefix means the Committee appointed as aforesaid for the purposes denoted or indicated by such prefix.

"Treasurer" means the person appointed pursuant to the By-laws as Honorary Treasurer of the Society.

"Foreign Secretary" means the person appointed pursuant to the By-laws as Honorary Foreign Secretary of the Society.

"The General Secretary" means the Secretary of the Society appointed by the Council, or the person acting in that capacity by the direction of the Council.

"The Editor" means the Editor of the Journal appointed by the Council, or the person or persons acting in that capacity by the direction of the Council.

"Sectional Officers" means the Chairman and Hon. Secretary of the several Local Sections.

"Group Officers" means the Chairman and Hon. Secretary of the several subject Groups.

"Member" means any Member of the Society.

"The Schedule" means the Schedule of Forms annexed to the By-laws.

"The Register" means the Register of the Society of 1881, continued as the Register of the Society.

Forms.

(4.) The forms set forth in the Schedule, and such other forms as the Council may from time to time authorise, shall be used in the several cases to which they are applicable, with such amendments, alterations, or additions thereto, if any, which the Council may from time to time determine, and all notes and directions printed thereon shall be read and construed as

part of such forms, and be observed accordingly, but it shall be sufficient if the forms are substantially followed, and no act or proceeding shall be invalid merely by reason of any formal defect.

PART II.—MEMBERS.

Proposal of Candidate.

(5.) Every person desirous of being admitted as a Member of the Society shall be duly proposed as a candidate for admission upon Form (A) set out in the Schedule, or such other form as the Council may from time to time prescribe. The proposal form shall be signed by two Members, to one of whom at the least the candidate shall be known personally, and every candidate shall make and subscribe the declaration therein contained—that, if elected, he agrees to be bound by the Charter and By-laws and by any Regulations made thereunder, and to further the objects of the Society.

Election of Members.

(6.) All proposal forms of Candidates, duly signed and subscribed as hereinbefore provided, received by the General Secretary prior to an Ordinary Meeting of Council, shall be considered thereat, and the Council may in their absolute discretion, by resolution passed by a majority of those present, elect or postpone the election of any candidate as a Member of the Society, or may refuse to elect any candidate whom they consider to be not a fit or proper person to be elected as aforesaid, and upon such election may also decide whether any Member so elected shall be required to pay for the year then current the whole or any part of the annual or other subscription or other fee hereafter provided, and thereupon the General Secretary shall give notice of such election and decision to the Member elected as aforesaid, and upon such notice and the payment of the said subscription or other fee, the person so elected shall, pursuant to the Charter and By-laws, become and continue to be subject to all the duties and obligations, and entitled to all the rights and privileges of a Member.

Register of Members.

(7.) The Register shall be continued as the Register of the Society by the entry therein by the General Secretary, or other person authorised by the Council, of the names of all persons elected Members as hereinbefore provided, together with the date of their several elections, and sufficient particulars of their several professions or occupations and addresses, and such particulars shall be amended or corrected as occasion may require.

Entrance Fee.

(8.) Except as otherwise decided by the Council, every Member shall, upon notice of his election, in addition to a subscription for the current year in which he is elected, or any payment in lieu thereof, pay to the Treasurer, or other person appointed by the Council to receive Members' fees or subscriptions, an entrance fee of One Guinea, or such other amount as may for the time being be prescribed by Regulations.

Annual Subscription.

(9.) Every Member shall on the first day of January in each year pay to the Treasurer, or other person as aforesaid, the sum of Two pounds ten shillings, or such other sum as the Council may prescribe by Regulations, and every Member shall upon his election pay the like amount as his subscription for the year current in which he is elected, or such part thereof as may be

decided by the Council, but in lieu of any such payment a Member may compound for that and all future payments, as hereinafter provided.

A Member joining under the age of 25 shall be entitled to pay a subscription of £2 per annum until attaining the age of 25, or for 3 years from date of election whichever is the longer period, but subject to the provisions that his application for Membership must be accompanied by (1) satisfactory evidence of age, and (2) a declaration that he is not joining the Society as a nominee of any firm or corporation but solely in his own interests as an individual member.

Life Compositions.

(10.) A Member, upon his election, or any other Member whose subscription is not in arrear, may at any time compound for all annual subscriptions by payment to the Treasurer, or other person as aforesaid, the sum following (that is to say):—

(a) A Member whose age does not exceed 30 years, the sum of £40.

(b) A Member whose age exceeds 30 years, the sum of £35, less such sum as is ascertained to be equal to one-fourth part of the total of the sums which have been paid by such Member as annual subscriptions after reaching the age of 30 years. But before accepting any compounding payment the Council shall require from any Member desirous of compounding such evidence of his age as they may think fit.

Subscriptions in Arrear.

(11.) Any Member whose annual subscription, payable on the first day of January, is unpaid on the first day of March next following, shall, while remaining subject to the duties and obligations, not be entitled to any of the rights of a Member until such subscription shall be paid and at any time after the first day of March, the General Secretary shall give notice to all members whose subscriptions are so in arrear, and if any Member on the next ensuing thirty-first day of December shall continue in arrear, such Member shall cease to be a Member, and his name shall then be removed from the Register by the General Secretary, but without prejudice to the right of the Council to recover any such arrears or to enforce any duty or obligation to which, as a Member, he may have become liable at the time of such removal, in any Court of competent jurisdiction. Notwithstanding anything in this By-law provided, the Council in the exercise of their sole discretion may, having regard to the circumstances in which the subscription of any Member shall be in arrear as aforesaid, postpone or remit the payment thereof, and continue such Member in full enjoyment of all rights of Membership as if such subscription had not at any time been or continued in arrear.

Certain Disqualifications of Members in Arrear.

(12.) A Member who has not paid before the first day of March any fee or subscription payable and due by him shall until payment be made be disqualified for nomination as President, Vice-President, and Ordinary Member of Council, and to continue in any such office, and to become or remain an *ex-officio* Member of Council, and to sign the form of nomination of an ordinary Member of Council.

Resignation of Members.

(13.) Any Member may at any time determine his Membership by notice in writing to that effect, sent to the General Secretary, but such notice in order to operate as a determination shall be accompanied by payment of any subscription or fee which at the date of the notice shall have become payable by the Member, and which remains unpaid.

Suspension or Determination of Membership by Council.

(14.) Any Member in respect of whom a complaint of misconduct is made to the Council, which complaint, the Member first having had an opportunity of being heard, is sufficiently established, in the opinion of the Council, may, by resolution of the Council as hereinafter provided, be suspended from rights of Membership for such period as the Council may decide, or the Council may in like manner decide that his Membership shall be determined, and there-

upon such Member shall cease to be a Member, and his name shall be removed from the Register; and in the event of it being brought to the notice of the Council that any Member has been adjudged by a Court of competent jurisdiction in the country in which he is alleged to have committed an offence to be guilty of an offence which in Great Britain or Ireland would be an indictable offence punishable by imprisonment, then, the Council may order his name to be removed from the Register, and thereupon he shall cease to be a Member. A resolution of the Council as aforesaid shall not be passed unless twelve or more Members of the Council are present at the meeting at which it is proposed and not less than two-thirds of those present vote in favour of such resolution.

Introduction of Visitors.

(15.) Every Member shall be at liberty to introduce, at any meeting of a Local Section or Subject Group at which the Member introducing is entitled to be present, such visitors as the rules of the Local Section or Subject Group may prescribe.

Restriction on use of Distinctive Title or Initials.

(16.) Any Member who shall persistently use after, or in conjunction with, his name, letters or initials which purport to indicate or convey that Membership of the Society confers upon him any degree, qualification, or authority to practise in any profession or calling, or a right to use any distinctive title, after notice from the General Secretary authorised by resolution of the Council to discontinue such use, may be deemed by the Council to be guilty of misconduct, but this By-law shall not prevent any Member from *bona fide* subscribing or describing himself as a Member of the Society or any office bearer thereof.

Re-admission of a former Member.

(17.) Any former Member whose Membership has ceased or been determined under any provisions of the By-laws, may apply for re-admission to Membership, and such application shall be considered and decided upon by the Council at the next ensuing Ordinary Meeting thereof in all respects as if it were a proposal for Membership of the Society, and if such application be granted, then after notice thereof by the General Secretary to the applicant, and upon making such payments and complying with such conditions, if any, which the Council may decide, the applicant shall be re-admitted to Membership, and shall again become subject and entitled to all the duties, obligations, and rights of a Member.

PART III.—THE COUNCIL.

Constitution.

(18.) The Council shall consist of:—

(a) Twenty-five elected Members of Council, comprising:—

(i.) A President;

(ii.) Twelve Vice-Presidents;

(iii.) Twelve ordinary Members of Council;

(b) *Ex-officio* Members of Council, comprising:—

(iv.) The Sectional and Group Officers;

(v.) The Treasurer, the Foreign Secretary;

all of whom shall be Members of the Society.

The elected Members of Council, except Members appointed to fill casual vacancies, shall be elected by ballot at the time, in the manner, and for the respective periods prescribed by the By-laws, and all Members of Council in office at the commencement of the By-laws shall in their several capacities continue in office, but subject to all incidences, whether as to powers, duties, retirement, re-election, nomination, election, or otherwise, as if they had been elected and were holding office pursuant to and under the several provisions of the By-laws applicable thereto.

The President.

(19.) The President shall be nominated from amongst the Members by the Council, and such member so nominated shall be submitted by the Council for election at the Annual General Meeting in manner hereinafter provided. He shall retire from office at the next ensuing Annual General Meeting, and shall be eligible for re-election, but a Member who has been elected or appointed President two years or one

year and a part of another year in succession, shall not be eligible for election as President before the Annual General Meeting next but one ensuing after his last retirement. A retiring President not nominated for re-election shall be nominated by the Council as one of the four Vice-Presidents to be submitted for election at the next ensuing Annual General Meeting.

In the event of the illness or absence from Great Britain of the President, the Council shall have power to elect a Chairman of Council who shall act as President.

Vice-Presidents.

(20.) The Vice-Presidents shall be nominated from amongst the Members by the Council, and such Members so nominated shall be submitted by the Council for election at the next ensuing Annual General Meeting in manner provided by the By-laws.

Four Vice-Presidents shall retire from office at each Annual General Meeting, none of whom shall be eligible for election as a Vice-President, or an ordinary Member of Council before the Annual General Meeting next ensuing after the said retirement, but a Member appointed Vice-President to fill a casual vacancy shall not, upon the expiration of the term for which he is so appointed, be ineligible as aforesaid.

All Vice-Presidents shall retire in rotation in accordance with the seniority of their respective terms of office, and if in ascertaining which four of them shall retire as aforesaid, it shall appear that there is equality of term of office in the case of more than four of them of the highest degree of seniority, or in the case of two or more of them of a lower degree of seniority required to make up four retiring Vice-Presidents, the Council shall decide which of them having such respective equality of term shall retire.

A Vice-President nominated as President in accordance with the last preceding By-law shall, upon election as President, vacate the office of Vice-President, and the vacancy thereby created shall be deemed to be a casual vacancy.

Ordinary Members of Council.

(21.) Ordinary members of Council shall be nominated from amongst the Members by the Members and such Members so nominated shall be submitted by the Council for election at the next ensuing Annual General Meeting in manner prescribed by the By-laws.

Four ordinary Members of Council shall retire from office at each Annual General Meeting, none of whom shall be eligible for election as an ordinary Member of Council before the Annual General Meeting next ensuing after the said retirement, but an ordinary Member of Council appointed to fill a casual vacancy shall not, upon the expiration of the term of office for which he is appointed, be ineligible as aforesaid.

All ordinary Members of Council shall retire in rotation, in accordance with the seniority of their respective terms of office, and if in ascertaining which four of them shall retire as aforesaid it shall appear that there is equality of term of office in the case of more than four of them of the highest degree of seniority, or in the case of two or more of them of a lower degree of seniority required to make up the four retiring ordinary Members of Council, the Council shall decide which of them having such respective equality of term shall retire.

An ordinary Member of Council nominated either as President or as Vice-President in accordance with the last two preceding By-laws respectively shall, upon election as President or Vice-President, as the case may be, vacate the office of ordinary Member of Council, and the vacancy, if any, thereby created shall be deemed to be a casual vacancy.

Qualification of an ordinary Member of Council.

(22.) An ordinary Member of Council shall be nominated by five or more Members upon Form (B) in the Schedule, a copy of which form shall be furnished by the General Secretary upon the written or verbal request of any Member, but a Member shall not be eligible to sign more than one such nomination form, and the Member nominated shall sign the declaration set forth on the form. A nomination shall be declared invalid by the Council if:—

- (a) The Member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the By-laws.
- (b) The nomination is not made on the authorised printed form, or substantially not in the manner directed thereon.
- (c) The nomination form is signed by less than five Members not disqualified, or not ineligible to nominate as provided by the By-laws.
- (d) The nomination form is not received before or upon the day appointed therefor.
- (e) The Member nominated has not signed the declaration printed upon the form.

A Member whose nomination aforesaid is declared to be invalid shall receive notice thereof from the General Secretary and shall not be submitted for election.

Council to Notify all Vacancies and Nominations by them.

(23.) In every year the Council shall cause a list to be prepared setting forth the names of all Members of the Council, showing which of them are due to retire at the next ensuing Annual General Meeting, and which (if any) of them are eligible for re-election, and such list shall be approved by the Council at any meeting thereof, not less than two months prior to the Annual General Meeting aforesaid, and the Council shall at the same meeting nominate the Members to be submitted to such meeting for election as President and Vice-Presidents respectively, and shall also appoint Members as Treasurer and Foreign Secretary respectively to take the places of the Treasurer and Foreign Secretary who will retire at the said General Meeting. The said list, together with the names of the Members nominated and appointed as aforesaid, shall be printed as a notice to Members, which notice shall contain a statement inviting Members to nominate the ordinary Members of Council to be elected at the said General Meeting, and appointing a day before or upon which such nominations shall be received by the General Secretary according to Form (B) in the Schedule, and the said notice, as approved, shall be sent to all the Members with, or in, the next issue of the Journal.

Nomination of ordinary Members of Council.

(24.) All nomination forms of ordinary Members of Council received by the General Secretary shall be considered by the Council at the meeting thereof next ensuing after the date appointed for their delivery, and the Members whose nominations are not then declared to be invalid, together with the Members nominated by the Council as President and Vice-Presidents respectively, shall be submitted for election at the next ensuing Annual General Meeting. But if the number of Members validly nominated shall be less than the number of vacancies, the Council shall thereupon nominate such Members as are requisite to make up the number required, and in that event, and also whenever the nominations considered and not declared to be invalid by the Council are equal to the number of vacancies, although the names of Members nominated in either case shall be submitted to the General Meeting, no ballot shall be taken thereon.

Election of Council.

(25.) The election of all elected Members of Council in whatever capacity, shall, except as provided by the By-laws, be by ballot taken upon the first day of each Annual General Meeting, and shall be conducted in manner and otherwise subject to such Regulations relating thereto as the Council may make, but a Member may record his votes either by delivering his ballot list personally or by post at the said General Meeting in accordance with the Regulations.

The Council in every year shall cause to be prepared, and shall send to all the Members not less than twenty-one days before the Annual General Meeting, a ballot list of the Council, showing the names of all Members thereof in their several capacities, and which of them are to retire, and setting forth separately thereon the names of Members submitted for election, in each capacity, and also the names of the Treasurer and Foreign Secretary appointed by the Council to succeed the retiring Treasurer and Foreign Secretary respectively, and the name of the retiring Auditor.

The ballot list shall be according to such form as the Council may from time to time authorise.

Meetings of Council.

(26.) One Ordinary Meeting of the Council at the least shall be held every month to transact such business relating to the affairs of the Society as may be necessary, except that if the Council so decide an Ordinary Meeting of the Council need not be held during the months of August and September, but a Special Meeting of the Council may be convened by the President at any time and shall be convened by the General Secretary whenever he shall receive a notice signed by not less than seven Members of Council calling upon him to convene such meeting, and stating the matter to be considered thereat, and notice thereof shall be given to all Members of the Council as and in the manner provided by the Standing Orders of the Council, and no other business shall be considered at such Special Meeting of Council. Except where otherwise provided by the Charter or the By-laws, any seven Members of the Council shall constitute a quorum.

Appointment of Committees.

(27.) Subject to the provisions of the Charter and the By-laws, the Council may appoint Committees from amongst themselves, and may delegate any of their powers to such Committees, and in furtherance of either the objects of the Society, may also appoint Committees composed partly of Members of the Council, and partly of non-members of the Council, and may fix the quorum and make rules for regulating the proceedings of any of the Committees aforesaid. The President and the Honorary Treasurer shall be Members of all Committees, and the General Secretary, unless the Council shall otherwise decide, shall act as Secretary to each Committee appointed as aforesaid.

Resignation of Member of Council.

(28.) Any Member of the Council may resign his office by notice in writing to the General Secretary of such his desire, and upon the acceptance thereof by the Council he shall cease to hold his said office, but not until then.

Vacation of Office of Member of Council

(29.) The office of any Member of the Council, whether elected or *ex-officio*, shall be deemed to be vacated for any of the following reasons:—

- (a) If any such Member ceases to be a Member of the Society, or his Membership thereof becomes suspended for any period, or determined as provided by the By-laws.
- (b) If any such Member becomes bankrupt, or suspends payment, or compounds with, or makes an assignment of his property for the benefit of his creditors.
- (c) If any such Member becomes a lunatic or is declared of unsound mind.

Casual Vacancies.

(30.) Any vacancy in the elected Members of Council, from whatever cause occurring, between any two Annual General Meetings, shall be filled by the Council. The Member appointed to fill a casual vacancy shall retire at the time when the person in whose stead he is appointed would in due course have retired if the office held by him had not become vacant, but the Member appointed shall be eligible for re-election unless it be otherwise provided in the By-laws.

Honorary Treasurer.

(31.) The Council shall appoint a Member as Honorary Treasurer of the Society, who shall, subject to the direction and control of the Council, receive and give receipts, and account for all subscriptions, fees, and other payments payable or due to or by the Society, and shall cause to be made, and shall, as occasion may require, submit to the Council a statement of the income and of current payments or expenditure which are, or ought to be, made by the Council, and shall prepare or cause to be prepared, in sufficient time to be submitted to the Annual General Meeting, a balance sheet showing the income and expenditure, and all liabilities and assets and investments of the Society for the year ending the thirty-first day of December prior to the said General Meeting, and as

far as possible a general statement of the financial affairs of the Society for the year then current.

Honorary Foreign Secretary.

(32.) The Council shall appoint a Member as Honorary Foreign Secretary of the Society, who shall, subject to the direction and control of the Council, have the management of such correspondence of the Society with Departments of State or Corporate Bodies, Societies, or persons of or in foreign countries as occasion may require, and he shall report to the Council on all matters connected therewith or relating thereto.

Appointment of Treasurer and Foreign Secretary.

(33.) The Treasurer and Foreign Secretary shall be appointed annually at the meeting of the Council at which the President and Vice Presidents are nominated, and except when appointed to fill a casual vacancy, shall remain in office from the next ensuing Annual General Meeting after their respective appointments, until the Annual General Meeting next following, and during such period shall be *ex-officio* Members of the Council. Any casual vacancy in either of the said offices shall be filled by the Council as soon as may be after the occurrence of the vacancy, but the Member appointed to fill such casual vacancy shall retire at the next ensuing Annual General Meeting after his appointment, and either of the said offices shall be deemed to be vacated for any of the reasons provided by the By-laws for the vacation of office of Member of Council.

The General Secretary.

(34.) The Council shall appoint a General Secretary of the Society of Chemical Industry at such remuneration and subject to such terms and conditions as they may from time to time decide, and may in their discretion determine the appointment of any such General Secretary, and appoint another General Secretary.

The Editor.

(35.) The Council shall appoint an Editor or Editors of the Journal, at such remuneration as they may from time to time decide, and may in their discretion determine the appointment of any such Editor and appoint another Editor. The Editors shall be responsible to the Council and subject thereto, and to the directions of any Committees delegated by the Council to manage or conduct the preparation or publication of the Journal, shall have the conduct of the literary management and the preparation of all matter, the editing, and the printing and publication of the Journal, and the organisation, control and direction of such literary or other staff as may be engaged on the Journal for the time being.

Council may make Regulations.

(36.) The Council may, except as otherwise provided by the Charter, make Regulations for carrying into effect the Charter and the By-laws and for the general management of the affairs of the Society, but a regulation shall not become operative until confirmed by a resolution passed by a majority of the Members present at a General Meeting at which such regulation has been submitted for consideration, and notice of such intended submission shall be given in the notice for such General Meeting, and any regulations so confirmed may be altered, amended, or repealed after notice given as aforesaid at an ensuing General Meeting summoned for that purpose in manner provided by the By-laws.

Standing Orders of Council.

(37.) Subject to any of the provisions of the Charter or the By-laws, the Council may for the due and proper regulation of its own proceedings make Standing Orders, and subject to any provisions therein contained, and relating thereto, may at any time add to, alter, amend, or rescind such Standing Orders.

PART IV.—LOCAL SECTIONS.

Formation of a Local Section.

(38.) A Local Section may be formed by the Council, whenever thirty or more Members residing in, or otherwise identified in interest with a place, locality

or district, whether situate within or without Great Britain or Ireland, make application in writing to the Council, signed by such Members, to cause a Local Register to be made for that purpose, and represent to the Council that the establishment of such Local Section will further more efficiently the objects of the Society. If the Council, upon consideration of such application, consider that it would be expedient to form such Local Section they may require the signatories to form a provisional committee, and to submit draft rules under which the business of the Local Section is intended to be managed and conducted, and may provisionally approve such draft rules with any modifications thereof which to the Council may seem requisite or desirable, and upon such provisional approval, to elect a committee and officers as hereinafter provided. Upon notice to the Council that such committee and officers have been elected at a meeting of any of the signatories and any other Members numbering in the whole not less than thirty, and that the draft rules approved by the Council as aforesaid have been adopted at such meeting, the Council shall allow the adopted rules as the rules of the said Local Section, and from the date of such allowance the said Local Section shall be deemed to be constituted in accordance with the Charter and By-laws.

Rules of a Local Section.

(39.) The rules of every Local Section shall contain the following provisions:—

- (i.) That the business of the Local Section shall be conducted by a Committee chosen from Members on the Register of the Local Section, consisting of a Chairman, Honorary Secretary, and ordinary Members of Committee as provided by Rules.
- (ii.) That any Member of the Society, whether resident at or otherwise interested in the place or locality where the Local Section is constituted, shall, upon application to the Honorary Secretary, be entitled to have his name entered upon the Register, and to become and remain a Member thereof upon payment of the annual sectional subscription, if any, for that and each succeeding year during which he remains a Member of the Local Section, without any entrance fee and without being elected.

Alterations of Rules.

(40.) Amendments in, alteration of, or additions to the rules of a Local Section shall be submitted to the Council, and shall not become operative or of any effect unless and until they have been allowed by the Council, and notice of such allowance has been given by the General Secretary.

Expenses of Local Section.

(41.) The expenses of a Local Section shall be defrayed out of the annual sectional subscriptions (if any) of the Members of such Section, but the Council in its discretion may defray the whole or may make a grant in aid thereof out of the General Funds of the Society, and a Local Section shall not pay, or incur, any expenses except reasonable sums for the clerical assistance, printing, stationery, advertising, reporting, and postage required for conducting the business, and the hire of rooms for meetings thereof without the previous sanction in writing of the Council, and an account of the income received and the expenditure paid or incurred by a Local Section during the year ending on the thirty-first day of December, shall on or before the fifteenth day of February in the following year be sent to the Council.

Communications to Local Sections.

(42.) The Committee of a Local Section, in furtherance of the objects of the Society, may invite or receive communications from any person, whether a Member of the Society or not, upon any subject coming within the scope of the said objects, and such communications may be made by the reading of an essay or paper, or the delivery of a lecture at a meeting of the Members of the Local Section, and every such communication—if intended for publication in the Journal—shall, before or after such meeting as the circumstances may require, be sent to the Council for their con-

sideration, and the Council may in their discretion, subject to any condition or to any by-law or rule relating thereto, cause the same, with or without any discussion thereof, or any condensed abstract thereof, to be published in the Journal.

Sectional Officers ex-officio Members of Council.

(43.) The Chairman and Honorary Secretary of every Local Section, duly constituted, shall become, and remain, during their respective terms of office *ex-officio* Members of the Council.

Restriction on Communications by Local Sections.

(44.) Neither the Committee of a Local Section nor any meeting thereof shall cause to be published, or authorise or countenance the publication of any notice upon any matter or subject whatsoever either in the name of the Society or in the name of the said Committee or Section, to the general public, except it relate wholly to the ordinary business of such Local Section, and except as provided in By-law 55, and all other notices and communications shall be conducted through or shall be subject to the express sanction of the Council.

Cesser of a Local Section.

(45.) The Council may, at a special meeting called for that purpose, declare by resolution that a Local Section shall be suspended in operation, or shall be dissolved:—

- (a) If it shall appear that the further continuance of the Section is not in accord with or conducive to the interests of the Society, or the furtherance of its objects.
- (b) Whenever three-fourths of the Members of the Local Section vote in favour of a resolution, proposed at a meeting called for the express purpose, that it is desirable such Section shall be suspended or dissolved.

PART V.—SUBJECT GROUPS.

Formation of a Subject Group.

(46.) A Subject Group may be formed by the Council, whenever thirty or more Members identified in interest with a particular subject within the objects of the Society make application in writing to the Council, signed by such Members, to cause a Register to be made for that purpose, and represent to the Council that the establishment of such Subject Group will further more efficiently the objects of the Society. If the Council, upon consideration of such application, consider that it would be expedient to form such Subject Group they may require the signatories to form a provisional committee, and to submit draft rules under which the business of the Subject Group is intended to be managed and conducted, and may provisionally approve such draft rules with any modifications thereof which to the Council may seem requisite or desirable, and upon such provisional approval, to elect a committee and officers as hereinafter provided. Upon notice to the Council that such committee and officers have been elected at a meeting of any of the signatories and any other Members numbering in the whole not less than thirty, and that the draft rules approved by the Council as aforesaid have been adopted at such meeting, the Council shall allow the adopted rules as the rules of the said Subject Group, and from the date of such allowance the said Subject Group shall be deemed to be constituted in accordance with the Charter and By-laws.

Rules of a Subject Group.

(47.) The Rules of every Subject Group shall contain the following provisions:—

- (i) That the business of the Subject Group shall be conducted by a Committee chosen from Members on the Register of the Subject Group consisting of a Chairman, Honorary Secretary, and ordinary members of Committee as provided by Rules.
- (ii.) That any Member of the Society shall, upon application to the Honorary Secretary, be entitled to have his name entered upon the Register, and to become and remain a Member of the Group upon payment of the annual Group subscription, if any, for that and each succeeding year during which he remains a

Member of the Subject Group without any entrance fee and without being elected.

- (iii.) Ordinary meetings of the Subject Group may include Conferences on special topics and may be held at the discretion of the Committee in centres where the subjects to be discussed have particular local industrial importance. The Secretary of the Local Section in the area of which the meetings are to be held is to be consulted as to the proposed dates of such meetings.

Alterations of Rules.

(48.) Amendments in, alterations of, or additions to the rules of a Subject Group shall be submitted to the Council, and shall not become operative or of any effect unless and until they have been allowed by the Council, and notice of such allowance has been given by the General Secretary.

Expenses of a Subject Group.

(49.) The expenses of a Subject Group shall be defrayed out of the annual Group subscriptions (if any) of the Members of such Group, but the Council in its discretion may defray the whole or may make a grant in aid thereof out of the General Funds of the Society, and a Subject Group shall not pay, or incur, any expenses except reasonable sums for the clerical assistance, printing, stationery, advertising, reporting, and postage required for conducting the business, and the hire of rooms for meetings thereof without the previous sanction in writing of the Council, and an account of the income received and the expenditure paid or incurred by a Subject Group during the year ending on the thirty-first day of December shall, on or before the fifteenth day of February in the following year, be sent to the Council.

Communications to Subject Groups.

(50.) The Committee of a Subject Group, in furtherance of the objects of the Society, may invite or receive communications from any person, whether a member of the Society or not, upon any subject coming within the scope of the said objects, and such communications may be made by the reading of an essay or paper, or the delivery of a lecture at a meeting of the Members of the Subject Group, and every such communication, if intended for publication in the Journal, shall, before or after such meeting, as the circumstances may require, be sent to the Council for their consideration, and the Council may in their discretion, subject to any condition or to any by-law or rule relating thereto, cause the same, with or without any discussion thereon, or any condensed abstract thereof, to be published in the Journal.

Group Officers ex-officio Members of Council.

(51.) The Chairman and Honorary Secretary of every Subject Group shall become, and remain, during their respective terms of office *ex officio* Members of the Council.

Restriction on Communications by Subject Groups.

(52.) Neither the Committee of a Subject Group nor any meeting thereof shall cause to be published, or authorise or countenance the publication of any notice upon any matter or subject whatsoever, except as provided in By-law 50, either in the name of the Society or in the name of the said Committee or Group, to the general public (except it relate wholly to the ordinary business of such Subject Group), and, except as aforesaid, all other notices and communications shall be conducted through or shall be subject to the express sanction of the Council.

Cesser of a Subject Group.

(53.) The Council may, at a special meeting called for that purpose, declare by resolution that a Subject Group shall be suspended in operation, or shall be dissolved :—

- If it shall appear that the further continuance of the Group is not in accord with or conducive to the interests of the Society, or the furtherance of its objects.
- Whenever three-fourths of the Members of the Subject Group vote in favour of a resolution, proposed at a meeting called for the express purpose, that it is desirable such Group shall be suspended or dissolved.

PART VI.—THE JOURNAL.

Conduct of the Journal.

(54.) The Journal shall be under the sole conduct and management in all respects of the Council, but they may at any time, subject to any rules and regulations made by them in reference thereto, appoint from amongst the Members any Committees which seem to them desirable to assist in such conduct or management, and subject as aforesaid, shall be at liberty to delegate any of their duties or functions as regards the Journal to any such Committee. The Council may also, in addition to the Editor or Editors, appoint upon and subject to such terms, and at such reasonable remuneration as they may decide, any managers, contributors, sub-editors, abstractors or other persons to assist in the compilation, preparation, and publication of the Journal, any of whom may or may not be Members.

Prior Right of Publication.

(55) It shall be a condition of acceptance of every communication made to any meeting of the Society or of a Local Section or Subject Group or submitted to the Council for publication in the Journal, whether made by a Member or not, that, unless there shall have been a previous agreement with the Council to the contrary, the Society shall thereby become entitled to a prior right of publication thereof, in whatever form the Council decide to make such publication in the Journal, for three months after its acceptance, and if the person by whom the communication is intended to be made is not a Member, he shall be informed of this condition by notice in writing from the General Secretary, or the Honorary Secretary of the Local Section or Subject Group. If, however, a communication to a Local Section or Subject Group is deemed by the Council not to be of general interest to the Members of the Society, the Committee of the Local Section or Subject Group shall have the right to publish and circulate such communication, subject to such rules as the Council may from time to time determine.

Publication of Journal.

(56.) The Council shall cause the Journal to be published and sent to the Members at least once in every month, upon such dates as they may think fit, and they may sell, or present gratuitously, or exchange copies, for any part thereof to or with any State or public department, or any institution, library, society, corporate body, company or person whatsoever.

Contents of Journal.

(57.) Nothing shall be printed or published in the Journal the printing and publication whereof has not been authorised by the Council, or any Committee appointed by them, and acting in such respect for and on behalf of the Council, but the Council or such Committee may authorise the printing and publication of any matter or thing coming within or relating to the objects of the Society, in such manner as they may determine, and may also accept and publish for payment any advertisements of which they may not disapprove, and all payments made therefor, or for any copies of the Journal sold as aforesaid, shall be credited to the cost of preparing, editing, printing, publishing, and distributing the Journal.

PART VII.—FINANCIAL.

Financial Management by Council.

(58.) The administration of the Funds, and of all financial matters of or relating to the Society, shall be conducted and managed by the Council, who shall act as a general Committee of Finance, but they may delegate any of their duties or functions in respect thereof to Committees composed of Members of and appointed by the Council, and such Committees shall act only subject to the control of the Council, and of any rules made by them in that behalf.

Annual Balance Sheet.

(59.) The Council shall receive and consider and may adopt the Annual Balance Sheet and General Financial Statement submitted by the Treasurer, and the report of the Auditors thereon, and shall, whether adopted or not, cause the Balance Sheet, Statement, and

Report aforesaid to be printed and sent to all the Members as a notice under the By-laws, and such notice shall be sent not later than the thirtieth day of June in every year.

Receipts and Payments.

(60.) All moneys due or payable to the Society shall be paid to and received by the Treasurer, or other person in that behalf appointed by the Council, and a receipt for every such payment shall be given in the name of the Society by the said Treasurer or other person. All moneys received as aforesaid shall be paid forthwith into the account of the Society kept at such bankers as may for the time being be appointed by the Council to be the bankers of the Society, and every cheque drawn on the said account shall be signed by two members of the Council duly authorised by the Council and countersigned by the General Secretary.

Borrowing Powers.

(61.) The Council may at any time, in the exercise of their discretion, borrow money temporarily, and may pay interest thereon, and may charge the property, assets, and investments of the Society, so far as they are enabled lawfully so to do, for the repayment and payment of such borrowed money and interest respectively.

Investments.

(62.) All life compositions, and all donations, bequests, and endowments, unless given subject to any other condition, or otherwise provided by any Deed or Trust relating thereto, shall, and all funds of the Society not needed immediately for the ordinary purposes thereof may be invested in the name of the Society or in the names of three Members of the Society who shall not be Members of the Council in any securities in which Trustees are from time to time authorised to invest by virtue of the Trustee Act, 1893, or any subsisting statutory modification thereof, with power, upon the authority and by the direction of the Council, from time to time to sell or vary such securities, and the Council may also from time to time place money on deposit with the bankers of the Society.

Auditor.

(63.) The Members present at the Annual General Meeting shall elect as Auditor of the Society, at such remuneration as the meeting shall determine, an Accountant who shall be a member of the Institute of Chartered Accountants in England and Wales, or a firm of Accountants the partners whereof are members of the said Institute, and the person or firm so elected shall, on election, become and remain the Auditor of the Society until the next Annual General Meeting, and then shall cease to be Auditor unless re-elected at such General Meeting.

Duties of Auditor.

(64.) The Auditor shall have access at all reasonable times to all the accounts and books of account in anywise relating to the income and expenditure and otherwise the financial affairs of the Society, and shall report upon the Balance Sheet prepared by the Treasurer to be submitted to the Annual General Meeting, as provided by the By-laws, and shall certify as to the correctness or otherwise of the liabilities, assets, and investments of the Society as existing upon the thirty-first day of December prior to the General Meeting at which the said Balance Sheet is to be presented, and his report and certificate as aforesaid, whatever its nature, shall be printed and sent to all the Members accompanying such Balance Sheet.

Casual Appointment and Removal of Auditor.

(65.) If at any time between two Annual General Meetings the office of Auditor becomes vacant, the Council may appoint an Auditor possessing the qualifications aforesaid, who shall remain in office until the next ensuing Annual General Meeting, and the Members may at any time after an Annual General Meeting, by a resolution passed by a majority of two-thirds of the votes of Members present and voting at an Extraordinary General Meeting at which not less than thirty Members are present and vote, remove any Auditor from office, and may, by a resolution

passed by a majority of the votes of Members present and voting at such meeting in number not less than aforesaid, elect at such remuneration as the meeting may then determine, any person or firm qualified to act as aforesaid.

PART VIII.—MEETINGS.

Annual General Meeting.

(66.) The Annual General Meeting for the transaction of the ordinary general business of the Society shall be held at such place and time in every year as the Council may determine.

The ordinary annual business of the Society shall comprise:—

The election of:—

Members of the Council; the Auditor;

And any other officers provided by the Charter or By-laws, to be elected at such meeting.

The reception and adoption of the Annual Report of the Council, and the Balance Sheet, Statement of Investments, and Financial Statement of the Treasurer submitted by the Council, together with the Auditor's report thereon.

And may include:—

An Address by the President.

Any communications accepted by the Council, and the discussion of the same if deemed desirable.

Conferences or discussions between the Members, or between Members and persons who are not Members, and visits to and inspection of works, manufactories, and other places of interest to the Members in furtherance of the objects of the Society.

Such other business as may be desirable and of which notice, according to the By-laws, has been duly given.

Extraordinary General Meeting.

(67.) The Council may, whenever they so decide, call an Extraordinary General Meeting of the Society, and such meeting shall be called by them on receiving a requisition in writing so to do signed by not less than thirty Members, and stating the object of the proposed meeting, but business other than that for which the meeting was called shall not be discussed or transacted at an Extraordinary General Meeting.

Notices of General Meetings.

(68.) Notice of the day, hour, and place of the commencement of any Annual General Meeting, shall be sent to all the Members two months at the least before such commencement. In the case of an Extraordinary General Meeting not less than fourteen days' notice thereof shall be sent either with or in the next succeeding issue of the Journal after the decision of the Council to call such meeting, or after the Council meeting next following the date upon which the requisition relating thereto was received by the General Secretary. The business to be considered at any such Extraordinary General Meeting shall be set forth on the said notice.

Quorum at General Meetings.

(69.) The business of an Annual General Meeting shall not commence until the Members present at the meeting, personally or by proxy, number thirty or upwards.

The business for which an Extraordinary General Meeting is called shall not commence until the Members present at the meeting, personally or by proxy, number thirty or upwards, and if within one hour after the time appointed for the commencement of such meeting the said number of Members are not present together, the meeting shall be thereupon and thereby dissolved. A Member may appoint another Member as his proxy at any meeting, by giving to the General Secretary notice in writing to that effect not less than 24 hours before the time fixed for such meeting.

Conduct of Business at Meetings.

(70.) Subject to the provisions of the By-laws relating thereto, the order of and the manner of conducting the business, and the way in which Members may record their votes thereat, or any other matter or thing of or relating to a General Meeting of the

Society not provided for in the Charter or By-laws, shall be regulated by rules made from time to time by the Council, but such rules or any addition thereto, alteration, amendment, suspension, or rescission thereof, shall, before becoming operative, be submitted to and approved at an Annual General Meeting.

Notice of Motion at Annual General Meeting to be given.

(71.) A Member wishing to bring before the Annual General Meeting any motion not relating to the ordinary annual business of the Society as aforesaid, shall give notice to the Council not less than one month before such Annual General Meeting, and no motion shall come before the meeting unless notice thereof has been so given, and on receipt of such notice of motion the Council shall give notice thereof in the next issue of the Journal.

Chairman of Meetings.

(72.) At all meetings of the Society the President for the time being, shall be Chairman, or in his absence the Chairman shall be elected from among the Members present.

Minutes to be Evidence.

(73.) Minutes shall be made in proper books, to be provided for the purpose, of all resolutions and proceedings of meetings of the Society or of the Council, or of each Local Section or Subject Group, and of any committee appointed by the Council or a Local Section or Subject Group, and every Minute signed by the Chairman of the meeting to which it relates, or by the Chairman of a subsequent meeting, shall be sufficient evidence of the facts stated therein.

PART IX.—MISCELLANEOUS.

Notices to Members.

(74.) Any notice required by the Charter or the By-laws to be given to Members whether relating in anywise to the affairs of the Society or of a Local Section may be a written or printed notice, and may be sent to Members either separately or in, or with, or if printed may be printed under the heading of "Notices," as part of the next issue of the Journal, as the Council may direct, and any notice shall be deemed to have been duly sent to a Member when such notice, or the Journal in which it is sent, or printed, and addressed to the last address of the Member appearing in the Register, has been put into the post. All notices shall be signed by the General Secretary.

Provisions as to Register.

(75.) The Register shall be kept by the General Secretary, subject to the direction of the Council, and the last address of any Member entered therein shall for the purpose of all notices and otherwise be deemed to be the address of that Member, but a Member may at any time, by notice in writing to the General Secretary, require his address last entered in the Register to be altered.

Award of a Medal by Society.

(76.) The practice of awarding a medal periodically to a person selected by the Council may be continued by the Council, and the Council in its discretion may for such purpose apply the funds of the Society, subject to the following conditions (that is to say):—

- (a) The medal shall be called "the Medal of the Society of Chemical Industry," and shall not be awarded more frequently than once in every two years.
- (b) The recipient of the medal shall be a person who, in the opinion of the Council, has rendered conspicuous service to Applied Chemistry by research, discovery, invention, or improvements in processes, or to the Society in furtherance of its objects, and may or may not be a Member, and may be of any nationality.
- (c) More than one medal shall not be awarded in any year.
- (d) The presentation of the medal shall be made to the recipient either in person or proxy at the Annual General Meeting for that year in which the Council decides to award the medal, and the

name of the recipient and the said service in respect of which the medal is awarded shall be notified to the Members in the notice of such General Meeting.

And the proposal to award a medal shall be considered at any meeting of the Council held after previous notice of such proposal.

Library.

(77.) Every paper, map, plan, drawing, or model presented to the Society shall become the property of the Society, except the presenter thereof shall stipulate to the contrary at the time of presentation, and all such, together with all publications presented to or purchased by the Society, and a set of bound copies of all issues of the Journal and indices thereof published by the Society of 1881, or the Society, shall be kept upon the premises of the Society for the use of the Members, in charge of a Librarian or other person appointed by the Council, and shall not be removed from such premises or kept elsewhere except upon the authority of the Council.

Pensions.

(78.) The Council may, with the consent of a General Meeting, make such provision for pensioning retired officers and servants receiving remuneration in respect of their several offices and services as to the Council may seem just.

Custody of Certain Books.

(79.) The Register and all Minute and Account books, or other books dealing with or recording the conduct of the business of the Society, except the business transacted by a Local Section, shall be kept upon the premises of the Society in the custody of the General Secretary or other person appointed by the Council for that purpose, and shall not be removed from the said premises or kept elsewhere except by the authority of the Council.

Custody of Charter Deeds and Securities.

(80.) The Charter and all deeds, securities, and other documents of title shall be deposited for safe keeping with the bankers of the Society, who shall, whenever required, produce them for purposes of inspection and verification to the Auditor.

Custody and use of Common Seal.

(81.) The Common Seal of the Society shall be kept in such custody as the Council may for the time being determine, and such Seal shall not be affixed to any document or instrument except by order of the Council, and in the presence of two Members thereof, and every such document or instrument when sealed shall be signed by the two Members of the Council in whose presence the Seal was affixed, and countersigned by the General Secretary.

Indemnity of Officers.

(82.) All Members of the Council, the Auditor, General Secretary, Editors, and other officers shall be indemnified by the Society in respect of all losses and proper expenses incurred by them in or about the discharge of their respective duties, except such as may arise from their own respective wilful default, and none of them shall be liable for any other Member of the Council, Auditor, General Secretary, Editor, or other officer, or for joining in any receipt or document, or for any act of conformity, and for any loss or expense caused to the Society except in the case of the like default.

Interpretation of By-laws.

(83.) Any difficulty arising out of the proceedings of Local Sections or Subject Groups, or as to the interpretation of the By-laws shall be referred to the Council for decision.

Alteration of By-laws.

(84.) A new By-law, or the alteration, suspension, or repeal of any existing By-law, may be proposed at any time by the Council, and shall be proposed by them after receipt of a requisition so to do signed by at least fifty Members. The proposal made shall in all cases be set forth in the notice of the meeting at which it is to be considered and decided.
